Chapter I

General Theorems

1 Probability theory

1.1 Random variables

1.1.1 Random experiment

Definition: A random experiment is any repeatable procedure that results in one ($\to$ Definition I/1.1.3) out of a well-defined set of possible outcomes.
- The set of possible outcomes is called sample space.
- A set of zero or more outcomes is called a random event ($\to$ Definition I/1.1.2).
- A function that maps from events to probabilities is called a probability function ($\to$ Definition I/1.3.1).

Together, sample space, event space and probability function characterize a random experiment.

- Wikipedia (2020): "Experiment (probability theory)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-11-19; URL: https://en.wikipedia.org/wiki/Experiment_(probability_theory).

Metadata: ID: D109 | shortcut: rexp | author: JoramSoch | date: 2020-11-19, 04:10.

1.1.2 Random event

Definition: A random event E is the outcome of a random experiment ($\to$ Definition I/1.1.1) which can be described by a statement that is either true or false.
- If the statement is true, the event is said to take place, denoted as E.
- If the statement is false, the complement of E occurs, denoted as $\overline{E}$.

In other words, a random event is a random variable ($\to$ Definition I/1.1.3) with two possible values (true and false, or 1 and 0). A random experiment ($\to$ Definition I/1.1.1) with two possible outcomes is called a Bernoulli trial ($\to$ Definition II/1.2.1).

Sources:
- Wikipedia (2020): "Event (probability theory)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-11-19; URL: https://en.wikipedia.org/wiki/Event_(probability_theory).

Metadata: ID: D110 | shortcut: reve | author: JoramSoch | date: 2020-11-19, 04:33.

1.1.3 Random variable

Definition: A random variable may be understood
- informally, as a real number $X \in \mathbb{R}$ whose value is the outcome of a random experiment ($\to$ Definition I/1.1.1);
- formally, as a measurable function ($\to$ Definition "meas-fct") X defined on a probability space ($\to$ Definition "prob-spc") $(\Omega, \mathcal{F}, P)$ that maps from a sample space Ω to the real numbers $\mathbb{R}$ using an event space $\mathcal{F}$ and a probability function ($\to$ Definition I/1.3.1) P;
- more broadly, as any random quantity X such as a random event ($\to$ Definition I/1.1.2), a random scalar ($\to$ Definition I/1.1.3), a random vector ($\to$ Definition I/1.1.4) or a random matrix ($\to$ Definition I/1.1.5).

Sources:

- Wikipedia (2020): "Random variable"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-27; URL: https://en.wikipedia.org/wiki/Random_variable#Definition.

Metadata: ID: D65 | shortcut: rvar | author: JoramSoch | date: 2020-05-27, 22:36.

1.1.4 Random vector

Definition: A random vector, also called "multivariate random variable", is an n-dimensional column vector $X \in \mathbb{R}^{n \times 1}$ whose entries are random variables ($\to$ Definition I/1.1.3).

Sources:
- Wikipedia (2020): "Multivariate random variable"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-27; URL: https://en.wikipedia.org/wiki/Multivariate_random_variable.

Metadata: ID: D66 | shortcut: rvec | author: JoramSoch | date: 2020-05-27, 22:44.

1.1.5 Random matrix

Definition: A random matrix, also called "matrix-valued random variable", is an $n \times p$ matrix $X \in \mathbb{R}^{n \times p}$ whose entries are random variables ($\to$ Definition I/1.1.3). Equivalently, a random matrix is an $n \times p$ matrix whose columns are n-dimensional random vectors ($\to$ Definition I/1.1.4).

Sources:
- Wikipedia (2020): "Random matrix"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-27; URL: https://en.wikipedia.org/wiki/Random_matrix.

Metadata: ID: D67 | shortcut: rmat | author: JoramSoch | date: 2020-05-27, 22:48.

1.1.6 Constant

Definition: A constant is a quantity which does not change and thus always has the same value. From a statistical perspective, a constant is a random variable ($\to$ Definition I/1.1.3) which is equal to its expected value ($\to$ Definition I/1.5.1)

$$X = \mathrm{E}(X) \tag{1}$$

or equivalently, whose variance ($\to$ Definition I/1.6.1) is zero

$$\mathrm{Var}(X) = 0 \; . \tag{2}$$

Sources:
- ProofWiki (2020): "Definition: Constant"; in: *ProofWiki*, retrieved on 2020-09-09; URL: https://proofwiki.org/wiki/Definition:Constant#Definition.

Metadata: ID: D96 | shortcut: const | author: JoramSoch | date: 2020-09-09, 01:30.

1.1.7 Discrete vs. continuous

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$. Then,
- X is called a discrete random variable, if $\mathcal{X}$ is either a finite set or a countably infinite set; in this case, X can be described by a probability mass function ($\rightarrow$ Definition I/1.4.1);
- X is called a continuous random variable, if $\mathcal{X}$ is an uncountably infinite set; if it is absolutely continuous, X can be described by a probability density function ($\rightarrow$ Definition I/1.4.4).

Sources:
- Wikipedia (2020): "Random variable"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-10-29; URL: https://en.wikipedia.org/wiki/Random_variable#Standard_case.

Metadata: ID: D105 | shortcut: rvar-disc | author: JoramSoch | date: 2020-10-29, 04:44.

1.1.8 Univariate vs. multivariate

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$. Then,
- X is called a two-valued random variable or random event ($\rightarrow$ Definition I/1.1.2), if $\mathcal{X}$ has exactly two elements, e.g. $\mathcal{X} = \left\{E, \overline{E}\right\}$ or $\mathcal{X} = \{\text{true}, \text{false}\}$ or $\mathcal{X} = \{1, 0\}$;
- X is called a univariate random variable or random scalar ($\rightarrow$ Definition I/1.1.3), if $\mathcal{X}$ is one-dimensional, i.e. (a subset of) the real numbers $\mathbb{R}$;
- X is called a multivariate random variable or random vector ($\rightarrow$ Definition I/1.1.4), if $\mathcal{X}$ is multi-dimensional, e.g. (a subset of) the n-dimensional Euclidean space $\mathbb{R}^n$;
- X is called a matrix-valued random variable or random matrix ($\rightarrow$ Definition I/1.1.5), if $\mathcal{X}$ is (a subset of) the set of $n \times p$ real matrices $\mathbb{R}^{n \times p}$.

Sources:
- Wikipedia (2020): "Multivariate random variable"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-11-06; URL: https://en.wikipedia.org/wiki/Multivariate_random_variable.

Metadata: ID: D106 | shortcut: rvar-uni | author: JoramSoch | date: 2020-11-06, 03:47.

1.2 Probability

1.2.1 Probability

Definition: Let E be a statement about an arbitrary event such as the outcome of a random experiment ($\rightarrow$ Definition I/1.1.1). Then, $p(E)$ is called the probability of E and may be interpreted as
- (objectivist interpretation of probability:) some physical state of affairs, e.g. the relative frequency of occurrence of E, when repeating the experiment ("Frequentist probability"); or
- (subjectivist interpretation of probability:) a degree of belief in E, e.g. the price at which someone would buy or sell a bet that pays 1 unit of utility if E and 0 if not E ("Bayesian probability").

Sources:
- Wikipedia (2020): "Probability"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-10; URL: https://en.wikipedia.org/wiki/Probability#Interpretations.

Metadata: ID: D48 | shortcut: prob | author: JoramSoch | date: 2020-05-10, 19:41.

1.2.2 Joint probability

Definition: Let A and B be two arbitrary statements about random variables ($\rightarrow$ Definition I/1.1.3), such as statements about the presence or absence of an event or about the value of a scalar, vector or matrix. Then, $p(A, B)$ is called the joint probability of A and B and is defined as the probability ($\rightarrow$ Definition I/1.2.1) that A and B are both true.

Sources:
- Wikipedia (2020): "Joint probability distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-10; URL: https://en.wikipedia.org/wiki/Joint_probability_distribution.

Metadata: ID: D49 | shortcut: prob-joint | author: JoramSoch | date: 2020-05-10, 19:49.

1.2.3 Marginal probability

Definition: Let A and X be two arbitrary statements about random variables ($\rightarrow$ Definition I/1.1.3), such as statements about the presence or absence of an event or about the value of a scalar, vector or matrix. Furthermore, assume a joint probability ($\rightarrow$ Definition I/1.2.2) distribution $p(A, X)$. Then, $p(A)$ is called the marginal probability of A and,
1) if X is a discrete random variable ($\rightarrow$ Definition I/1.1.3) with domain $\mathcal{X}$, is given by

$$p(A) = \sum_{x \in \mathcal{X}} p(A, x) \; ; \tag{1}$$

2) if X is a continuous random variable ($\rightarrow$ Definition I/1.1.3) with domain $\mathcal{X}$, is given by

$$p(A) = \int_{\mathcal{X}} p(A, x) \, \mathrm{d}x \; . \tag{2}$$

Sources:
- Wikipedia (2020): "Marginal distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-10; URL: https://en.wikipedia.org/wiki/Marginal_distribution#Definition.

Metadata: ID: D50 | shortcut: prob-marg | author: JoramSoch | date: 2020-05-10, 20:01.

1.2.4 Conditional probability

Definition: Let A and B be two arbitrary statements about random variables ($\rightarrow$ Definition I/1.1.3), such as statements about the presence or absence of an event or about the value of a scalar, vector or matrix. Furthermore, assume a joint probability ($\rightarrow$ Definition I/1.2.2) distribution $p(A, B)$. Then, $p(A|B)$ is called the conditional probability that A is true, given that B is true, and is given by

$$p(A|B) = \frac{p(A, B)}{p(B)} \tag{1}$$

where $p(B)$ is the marginal probability ($\rightarrow$ Definition I/1.2.3) of B.

Sources:
- Wikipedia (2020): "Conditional probability"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-10; URL: https://en.wikipedia.org/wiki/Conditional_probability#Definition.

Metadata: ID: D51 | shortcut: prob-cond | author: JoramSoch | date: 2020-05-10, 20:06.

1.2.5   Exceedance probability

Definition: Let $X = \{X_1, \ldots, X_n\}$ be a set of n random variables ($\rightarrow$ Definition I/1.1.3) which the joint probability distribution ($\rightarrow$ Definition I/1.3.2) $p(X) = p(X_1, \ldots, X_n)$. Then, the exceedance probability for random variable X_i is the probability ($\rightarrow$ Definition I/1.2.1) that X_i is larger than all other random variables X_j, $j \neq i$:

$$\begin{aligned}
\varphi(X_i) &= \Pr\left(\forall j \in \{1, \ldots, n | j \neq i\} : X_i > X_j\right) \\
&= \Pr\left(\bigwedge_{j \neq i} X_i > X_j\right) \\
&= \Pr\left(X_i = \max(\{X_1, \ldots, X_n\})\right) \\
&= \int_{X_i = \max(X)} p(X)\, \mathrm{d}X \ .
\end{aligned} \tag{1}$$

Metadata: ID: D103 | shortcut: prob-exc | author: JoramSoch | date: 2020-10-22, 04:36.

1.2.6   Statistical independence

Definition: Generally speaking, random variables ($\rightarrow$ Definition I/1.1.3) are statistically independent, if their joint probability ($\rightarrow$ Definition I/1.2.2) can be expressed in terms of their marginal probabilities ($\rightarrow$ Definition I/1.2.3).

1) A set of discrete random variables ($\rightarrow$ Definition I/1.1.3) $X_1, \ldots, X_n$ with possible values $\mathcal{X}_1, \ldots, \mathcal{X}_n$ is called statistically independent, if

$$p(X_1 = x_1, \ldots, X_n = x_n) = \prod_{i=1}^{n} p(X_i = x_i) \quad \text{for all } x_i \in \mathcal{X}_i, \ i = 1, \ldots, n \tag{1}$$

where $p(x_1, \ldots, x_n)$ are the joint probabilities ($\rightarrow$ Definition I/1.2.2) of $X_1, \ldots, X_n$ and $p(x_i)$ are the marginal probabilities ($\rightarrow$ Definition I/1.2.3) of X_i.

2) A set of continuous random variables ($\rightarrow$ Definition I/1.1.3) $X_1, \ldots, X_n$ defined on the domains $\mathcal{X}_1, \ldots, \mathcal{X}_n$ is called statistically independent, if

$$F_{X_1, \ldots, X_n}(x_1, \ldots, x_n) = \prod_{i=1}^{n} F_{X_i}(x_i) \quad \text{for all } x_i \in \mathcal{X}_i, \ i = 1, \ldots, n \tag{2}$$

or equivalently, if the probability densities ($\rightarrow$ Definition I/1.4.4) exist, if

$$f_{X_1,\ldots,X_n}(x_1,\ldots,x_n) = \prod_{i=1}^{n} f_{X_i}(x_i) \quad \text{for all } x_i \in \mathcal{X}_i,\ i = 1,\ldots,n \tag{3}$$

where F are the joint ($\rightarrow$ Definition I/1.3.2) or marginal ($\rightarrow$ Definition I/1.3.3) cumulative distribution functions ($\rightarrow$ Definition I/1.4.8) and f are the respective probability density functions ($\rightarrow$ Definition I/1.4.4).

Sources:
- Wikipedia (2020): "Independence (probability theory)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-06-06; URL: https://en.wikipedia.org/wiki/Independence_(probability_theory) #Definition.

Metadata: ID: D75 | shortcut: ind | author: JoramSoch | date: 2020-06-06, 07:16.

1.2.7 Conditional independence

Definition: Generally speaking, random variables ($\rightarrow$ Definition I/1.1.3) are conditionally independent given another random variable, if they are statistically independent ($\rightarrow$ Definition I/1.2.6) in their conditional probability distributions ($\rightarrow$ Definition I/1.3.4) given this random variable.

1) A set of discrete random variables ($\rightarrow$ Definition I/1.1.7) $X_1,\ldots,X_n$ with possible values $\mathcal{X}_1,\ldots,\mathcal{X}_n$ is called conditionally independent given the random variable Y with possible values $\mathcal{Y}$, if

$$p(X_1 = x_1,\ldots,X_n = x_n|Y = y) = \prod_{i=1}^{n} p(X_i = x_i|Y = y) \quad \text{for all } x_i \in \mathcal{X}_i \quad \text{and all } y \in \mathcal{Y} \tag{1}$$

where $p(x_1,\ldots,x_n|y)$ are the joint (conditional) probabilities ($\rightarrow$ Definition I/1.2.2) of $X_1,\ldots,X_n$ given Y and $p(x_i)$ are the marginal (conditional) probabilities ($\rightarrow$ Definition I/1.2.3) of X_i given Y.

2) A set of continuous random variables ($\rightarrow$ Definition I/1.1.7) $X_1,\ldots,X_n$ with possible values $\mathcal{X}_1,\ldots,\mathcal{X}_n$ is called conditionally independent given the random variable Y with possible values $\mathcal{Y}$, if

$$F_{X_1,\ldots,X_n|Y=y}(x_1,\ldots,x_n) = \prod_{i=1}^{n} F_{X_i|Y=y}(x_i) \quad \text{for all } x_i \in \mathcal{X}_i \quad \text{and all } y \in \mathcal{Y} \tag{2}$$

or equivalently, if the probability densities ($\rightarrow$ Definition I/1.4.4) exist, if

$$f_{X_1,\ldots,X_n|Y=y}(x_1,\ldots,x_n) = \prod_{i=1}^{n} f_{X_i|Y=y}(x_i) \quad \text{for all } x_i \in \mathcal{X}_i \quad \text{and all } y \in \mathcal{Y} \tag{3}$$

where F are the joint (conditional) ($\rightarrow$ Definition I/1.3.2) or marginal (conditional) ($\rightarrow$ Definition I/1.3.3) cumulative distribution functions ($\rightarrow$ Definition I/1.4.8) and f are the respective probability density functions ($\rightarrow$ Definition I/1.4.4).

Sources:

- Wikipedia (2020): "Conditional independence"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-11-19; URL: https://en.wikipedia.org/wiki/Conditional_independence#Conditional_independence_ of_random_variables.

Metadata: ID: D112 | shortcut: ind-cond | author: JoramSoch | date: 2020-11-19, 05:40.

1.3 Probability distributions

1.3.1 Probability distribution

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) with the set of possible outcomes $\mathcal{X}$. Then, a probability distribution of X is a mathematical function that gives the probabilities ($\rightarrow$ Definition I/1.2.1) of occurrence of all possible outcomes $x \in \mathcal{X}$ of this random variable.

Sources:
- Wikipedia (2020): "Probability distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-17; URL: https://en.wikipedia.org/wiki/Probability_distribution.

Metadata: ID: D55 | shortcut: dist | author: JoramSoch | date: 2020-05-17, 20:23.

1.3.2 Joint distribution

Definition: Let X and Y be random variables ($\rightarrow$ Definition I/1.1.3) with sets of possible outcomes $\mathcal{X}$ and $\mathcal{Y}$. Then, a joint distribution of X and Y is a probability distribution ($\rightarrow$ Definition I/1.3.1) that specifies the probability of the event that $X = x$ and $Y = y$ for each possible combination of $x \in \mathcal{X}$ and $y \in \mathcal{Y}$.
- The joint distribution of two scalar random variables ($\rightarrow$ Definition I/1.1.3) is called a bivariate distribution.
- The joint distribution of a random vector ($\rightarrow$ Definition I/1.1.4) is called a multivariate distribution.
- The joint distribution of a random matrix ($\rightarrow$ Definition I/1.1.5) is called a matrix-variate distribution.

Sources:
- Wikipedia (2020): "Joint probability distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-17; URL: https://en.wikipedia.org/wiki/Joint_probability_distribution.

Metadata: ID: D56 | shortcut: dist-joint | author: JoramSoch | date: 2020-05-17, 20:43.

1.3.3 Marginal distribution

Definition: Let X and Y be random variables ($\rightarrow$ Definition I/1.1.3) with sets of possible outcomes $\mathcal{X}$ and $\mathcal{Y}$. Then, the marginal distribution of X is a probability distribution ($\rightarrow$ Definition I/1.3.1) that specifies the probability of the event that $X = x$ irrespective of the value of Y for each possible value $x \in \mathcal{X}$. The marginal distribution can be obtained from the joint distribution ($\rightarrow$ Definition I/1.3.2) of X and Y using the law of marginal probability ($\rightarrow$ Definition I/1.2.3).

Sources:

- Wikipedia (2020): "Marginal distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-17; URL: https://en.wikipedia.org/wiki/Marginal_distribution.

Metadata: ID: D57 | shortcut: dist-marg | author: JoramSoch | date: 2020-05-17, 21:02.

1.3.4 Conditional distribution

Definition: Let X and Y be random variables ($\rightarrow$ Definition I/1.1.3) with sets of possible outcomes $\mathcal{X}$ and $\mathcal{Y}$. Then, the conditional distribution of X given that Y is a probability distribution ($\rightarrow$ Definition I/1.3.1) that specifies the probability of the event that $X = x$ given that $Y = y$ for each possible combination of $x \in \mathcal{X}$ and $y \in \mathcal{Y}$. The conditional distribution of X can be obtained from the joint distribution ($\rightarrow$ Definition I/1.3.2) of X and Y and the marginal distribution ($\rightarrow$ Definition I/1.3.3) of Y using the law of conditional probability ($\rightarrow$ Definition I/1.2.4).

Sources:
- Wikipedia (2020): "Conditional probability distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-17; URL: https://en.wikipedia.org/wiki/Conditional_probability_distribution.

Metadata: ID: D58 | shortcut: dist-cond | author: JoramSoch | date: 2020-05-17, 21:25.

1.3.5 Sampling distribution

Definition: Let there be a random sample ($\rightarrow$ Definition "samp") with finite sample size ($\rightarrow$ Definition "samp-size"). Then, the probability distribution ($\rightarrow$ Definition I/1.3.1) of a given statistic ($\rightarrow$ Definition "stat") computed from this sample, e.g. a test statistic ($\rightarrow$ Definition I/4.3.5), is called a sampling distribution.

Sources:
- Wikipedia (2021): "Sampling distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-31; URL: https://en.wikipedia.org/wiki/Sampling_distribution.

Metadata: ID: D140 | shortcut: dist-samp | author: JoramSoch | date: 2021-03-31, 09:43.

1.4 Probability functions

1.4.1 Probability mass function

Definition: Let X be a discrete ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$. Then, $f_X(x) : \mathbb{R} \rightarrow [0, 1]$ is the probability mass function (PMF) of X, if

$$f_X(x) = 0 \tag{1}$$

for all $x \notin \mathcal{X}$,

$$\Pr(X = x) = f_X(x) \tag{2}$$

for all $x \in \mathcal{X}$ and

$$\sum_{x \in \mathcal{X}} f_X(x) = 1 \ . \tag{3}$$

Sources:
- Wikipedia (2020): "Probability mass function"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-13; URL: https://en.wikipedia.org/wiki/Probability_mass_function.

Metadata: ID: D9 | shortcut: pmf | author: JoramSoch | date: 2020-02-13, 19:09.

1.4.2   Probability mass function of strictly increasing function

Theorem: Let X be a discrete ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let $g(x)$ be a strictly increasing function on the support of X. Then, the probability mass function ($\rightarrow$ Definition I/1.4.1) of $Y = g(X)$ is given by

$$f_Y(y) = \begin{cases} f_X(g^{-1}(y)) \ , & \text{if } y \in \mathcal{Y} \\[2mm] 0 \ , & \text{if } y \notin \mathcal{Y} \end{cases} \tag{1}$$

where $g^{-1}(y)$ is the inverse function of $g(x)$ and $\mathcal{Y}$ is the set of possible outcomes of Y:

$$\mathcal{Y} = \{y = g(x) : x \in \mathcal{X}\} \ . \tag{2}$$

Proof: Because a strictly increasing function is invertible, the probability mass function ($\rightarrow$ Definition I/1.4.1) of Y can be derived as follows:

$$\begin{aligned} f_Y(y) &= \Pr(Y = y) \\ &= \Pr(g(X) = y) \\ &= \Pr(X = g^{-1}(y)) \\ &= f_X(g^{-1}(y)) \ . \end{aligned} \tag{3}$$

Sources:

Metadata: ID: P184 | shortcut: pmf-sifct | author: JoramSoch | date: 2020-10-29, 05:55.

1.4.3   Probability mass function of strictly decreasing function

Theorem: Let X be a discrete ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let $g(x)$ be a strictly decreasing function on the support of X. Then, the probability mass function ($\rightarrow$ Definition I/1.4.1) of $Y = g(X)$ is given by

$$f_Y(y) = \begin{cases} f_X(g^{-1}(y)) \,, & \text{if } y \in \mathcal{Y} \\ 0 \,, & \text{if } y \notin \mathcal{Y} \end{cases} \tag{1}$$

where $g^{-1}(y)$ is the inverse function of $g(x)$ and $\mathcal{Y}$ is the set of possible outcomes of Y:

$$\mathcal{Y} = \{y = g(x) : x \in \mathcal{X}\} \,. \tag{2}$$

Proof: Because a strictly decreasing function is invertible, the probability mass function ($\rightarrow$ Definition I/1.4.1) of Y can be derived as follows:

$$\begin{aligned} f_Y(y) &= \Pr(Y = y) \\ &= \Pr(g(X) = y) \\ &= \Pr(X = g^{-1}(y)) \\ &= f_X(g^{-1}(y)) \,. \end{aligned} \tag{3}$$

Metadata: ID: P187 | shortcut: pmf-sdfct | author: JoramSoch | date: 2020-11-06, 04:21.

1.4.4 Probability density function

Definition: Let X be a continuous ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$. Then, $f_X(x) : \mathbb{R} \rightarrow \mathbb{R}$ is the probability density function (PDF) of X, if

$$f_X(x) \geq 0 \tag{1}$$

for all $x \in \mathbb{R}$,

$$\Pr(X \in A) = \int_A f_X(x)\,\mathrm{d}x \tag{2}$$

for any $A \subset \mathcal{X}$ and

$$\int_{\mathcal{X}} f_X(x)\,\mathrm{d}x = 1 \,. \tag{3}$$

Sources:
- Wikipedia (2020): "Probability density function"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-13; URL: https://en.wikipedia.org/wiki/Probability_density_function.

Metadata: ID: D10 | shortcut: pdf | author: JoramSoch | date: 2020-02-13, 19:26.

1.4.5   Probability density function of strictly increasing function

Theorem: Let X be a continuous ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let $g(x)$ be a strictly increasing function on the support of X. Then, the probability density function ($\rightarrow$ Definition I/1.4.4) of $Y = g(X)$ is given by

$$f_Y(y) = \begin{cases} f_X(g^{-1}(y)) \, \frac{\mathrm{d}g^{-1}(y)}{\mathrm{d}y} \,, & \text{if } y \in \mathcal{Y} \\ 0 \,, & \text{if } y \notin \mathcal{Y} \end{cases} \tag{1}$$

where $g^{-1}(y)$ is the inverse function of $g(x)$ and $\mathcal{Y}$ is the set of possible outcomes of Y:

$$\mathcal{Y} = \{y = g(x) : x \in \mathcal{X}\} \,. \tag{2}$$

Proof: The cumulative distribution function of a strictly increasing function ($\rightarrow$ Proof I/1.4.9) is

$$F_Y(y) = \begin{cases} 0 \,, & \text{if } y < \min(\mathcal{Y}) \\ F_X(g^{-1}(y)) \,, & \text{if } y \in \mathcal{Y} \\ 1 \,, & \text{if } y > \max(\mathcal{Y}) \end{cases} \tag{3}$$

Because the probability density function is the first derivative of the cumulative distribution function ($\rightarrow$ Proof I/1.4.7)

$$f_X(x) = \frac{\mathrm{d}F_X(x)}{\mathrm{d}x} \,, \tag{4}$$

the probability density function ($\rightarrow$ Definition I/1.4.4) of Y can be derived as follows:
1) If y does not belong to the support of Y, $F_Y(y)$ is constant, such that

$$f_Y(y) = 0, \quad \text{if} \quad y \notin \mathcal{Y} \,. \tag{5}$$

2) If y belongs to the support of Y, then $f_Y(y)$ can be derived using the chain rule:

$$\begin{aligned} f_Y(y) &\overset{(4)}{=} \frac{\mathrm{d}}{\mathrm{d}y} F_Y(y) \\ &\overset{(3)}{=} \frac{\mathrm{d}}{\mathrm{d}y} F_X(g^{-1}(y)) \\ &= f_X(g^{-1}(y)) \frac{\mathrm{d}g^{-1}(y)}{\mathrm{d}y} \,. \end{aligned} \tag{6}$$

Taking together (5) and (6), eventually proves (1).

1.4.6 Probability density function of strictly decreasing function

Theorem: Let X be a continuous ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let $g(x)$ be a strictly decreasing function on the support of X. Then, the probability density function ($\rightarrow$ Definition I/1.4.4) of $Y = g(X)$ is given by

$$f_Y(y) = \begin{cases} -f_X(g^{-1}(y)) \frac{\mathrm{d}g^{-1}(y)}{\mathrm{d}y} , & \text{if } y \in \mathcal{Y} \\ 0 , & \text{if } y \notin \mathcal{Y} \end{cases} \tag{1}$$

where $g^{-1}(y)$ is the inverse function of $g(x)$ and $\mathcal{Y}$ is the set of possible outcomes of Y:

$$\mathcal{Y} = \{y = g(x) : x \in \mathcal{X}\} . \tag{2}$$

Proof: The cumulative distribution function of a strictly decreasing function ($\rightarrow$ Proof I/1.4.9) is

$$F_Y(y) = \begin{cases} 1 , & \text{if } y > \max(\mathcal{Y}) \\ 1 - F_X(g^{-1}(y)) + \Pr(X = g^{-1}(y)) , & \text{if } y \in \mathcal{Y} \\ 0 , & \text{if } y < \min(\mathcal{Y}) \end{cases} \tag{3}$$

Note that for continuous random variables, the probability ($\rightarrow$ Definition I/1.4.4) of point events is

$$\Pr(X = a) = \int_a^a f_X(x) \, \mathrm{d}x = 0 . \tag{4}$$

Because the probability density function is the first derivative of the cumulative distribution function ($\rightarrow$ Proof I/1.4.7)

$$f_X(x) = \frac{\mathrm{d}F_X(x)}{\mathrm{d}x} , \tag{5}$$

the probability density function ($\rightarrow$ Definition I/1.4.4) of Y can be derived as follows:
1) If y does not belong to the support of Y, $F_Y(y)$ is constant, such that

$$f_Y(y) = 0, \quad \text{if} \quad y \notin \mathcal{Y} . \tag{6}$$

2) If y belongs to the support of Y, then $f_Y(y)$ can be derived using the chain rule:

$$\begin{aligned} f_Y(y) &\overset{(5)}{=} \frac{\mathrm{d}}{\mathrm{d}y} F_Y(y) \\ &\overset{(3)}{=} \frac{\mathrm{d}}{\mathrm{d}y} \left[1 - F_X(g^{-1}(y)) + \Pr(X = g^{-1}(y)) \right] \\ &\overset{(4)}{=} \frac{\mathrm{d}}{\mathrm{d}y} \left[1 - F_X(g^{-1}(y)) \right] \\ &= -\frac{\mathrm{d}}{\mathrm{d}y} F_X(g^{-1}(y)) \\ &= -f_X(g^{-1}(y)) \frac{\mathrm{d}g^{-1}(y)}{\mathrm{d}y} . \end{aligned} \tag{7}$$

Taking together (6) and (7), eventually proves (1).

1.4.7 Probability density function in terms of cumulative distribution function

Theorem: Let X be a continuous ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3). Then, the probability distribution function ($\rightarrow$ Definition I/1.4.4) of X is the first derivative of the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of X:

$$f_X(x) = \frac{\mathrm{d}F_X(x)}{\mathrm{d}x} \ . \tag{1}$$

Proof: The cumulative distribution function in terms of the probability density function of a continuous random variable ($\rightarrow$ Proof I/1.4.12) is given by:

$$F_X(x) = \int_{-\infty}^{x} f_X(t)\,\mathrm{d}t, \ x \in \mathbb{R} \ . \tag{2}$$

Taking the derivative with respect to x, we have:

$$\frac{\mathrm{d}F_X(x)}{\mathrm{d}x} = \frac{\mathrm{d}}{\mathrm{d}x} \int_{-\infty}^{x} f_X(t)\,\mathrm{d}t \ . \tag{3}$$

The fundamental theorem of calculus states that, if $f(x)$ is a continuous real-valued function defined on the interval $[a, b]$, then it holds that

$$F(x) = \int_{a}^{x} f(t)\,\mathrm{d}t \quad \Rightarrow \quad F'(x) = f(x) \quad \text{for all} \quad x \in (a, b) \ . \tag{4}$$

Applying (4) to (2), it follows that

$$F_X(x) = \int_{-\infty}^{x} f_X(t)\,\mathrm{d}t \quad \Rightarrow \quad \frac{\mathrm{d}F_X(x)}{\mathrm{d}x} = f_X(x) \quad \text{for all} \quad x \in \mathbb{R} \ . \tag{5}$$

1.4.8 Cumulative distribution function

Definition: The cumulative distribution function (CDF) of a random variable ($\rightarrow$ Definition I/1.1.3) X at a given value x is defined as the probability ($\rightarrow$ Definition I/1.2.1) that X is smaller than x:

$$F_X(x) = \Pr(X \leq x) \ . \tag{1}$$

1) If X is a discrete ($\to$ Definition I/1.1.7) random variable ($\to$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and the probability mass function ($\to$ Definition I/1.4.1) $f_X(x)$, then the cumulative distribution function is the function ($\to$ Proof I/1.4.11) $F_X(x) : \mathbb{R} \to [0,1]$ with

$$F_X(x) = \sum_{\substack{t \in \mathcal{X} \\ t \leq x}} f_X(t) \; . \tag{2}$$

2) If X is a continuous ($\to$ Definition I/1.1.7) random variable ($\to$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and the probability density function ($\to$ Definition I/1.4.4) $f_X(x)$, then the cumulative distribution function is the function ($\to$ Proof I/1.4.12) $F_X(x) : \mathbb{R} \to [0,1]$ with

$$F_X(x) = \int_{-\infty}^{x} f_X(t) \, \mathrm{d}t \; . \tag{3}$$

Sources:
- Wikipedia (2020): "Cumulative distribution function"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-17; URL: https://en.wikipedia.org/wiki/Cumulative_distribution_function# Definition.

1.4.9 Cumulative distribution function of strictly increasing function

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let $g(x)$ be a strictly increasing function on the support of X. Then, the cumulative distribution function ($\to$ Definition I/1.4.8) of $Y = g(X)$ is given by

$$F_Y(y) = \begin{cases} 0 \; , & \text{if } y < \min(\mathcal{Y}) \\ F_X(g^{-1}(y)) \; , & \text{if } y \in \mathcal{Y} \\ 1 \; , & \text{if } y > \max(\mathcal{Y}) \end{cases} \tag{1}$$

where $g^{-1}(y)$ is the inverse function of $g(x)$ and $\mathcal{Y}$ is the set of possible outcomes of Y:

$$\mathcal{Y} = \{y = g(x) : x \in \mathcal{X}\} \; . \tag{2}$$

Proof: The support of Y is determined by $g(x)$ and by the set of possible outcomes of X. Moreover, if $g(x)$ is strictly increasing, then $g^{-1}(y)$ is also strictly increasing. Therefore, the cumulative distribution function ($\to$ Definition I/1.4.8) of Y can be derived as follows:
1) If y is lower than the lowest value ($\to$ Definition I/1.11.1) Y can take, then $\Pr(Y \leq y) = 0$, so

$$F_Y(y) = 0, \quad \text{if} \quad y < \min(\mathcal{Y}) \; . \tag{3}$$

2) If y belongs to the support of Y, then $F_Y(y)$ can be derived as follows:

$$
\begin{aligned}
F_Y(y) &= \Pr(Y \leq y) \\
&= \Pr(g(X) \leq y) \\
&= \Pr(X \leq g^{-1}(y)) \\
&= F_X(g^{-1}(y)) \ .
\end{aligned}
\tag{4}
$$

3) If y is higher than the highest value ($\to$ Definition I/1.11.2) Y can take, then $\Pr(Y \leq y) = 1$, so

$$
F_Y(y) = 1, \quad \text{if} \quad y > \max(\mathcal{Y}) \ .
\tag{5}
$$

Taking together (3), (4), (5), eventually proves (1).

1.4.10 Cumulative distribution function of strictly decreasing function

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let $g(x)$ be a strictly decreasing function on the support of X. Then, the cumulative distribution function ($\to$ Definition I/1.4.8) of $Y = g(X)$ is given by

$$
F_Y(y) =
\begin{cases}
1 \ , & \text{if } y > \max(\mathcal{Y}) \\
1 - F_X(g^{-1}(y)) + \Pr(X = g^{-1}(y)) \ , & \text{if } y \in \mathcal{Y} \\
0 \ , & \text{if } y < \min(\mathcal{Y})
\end{cases}
\tag{1}
$$

where $g^{-1}(y)$ is the inverse function of $g(x)$ and $\mathcal{Y}$ is the set of possible outcomes of Y:

$$
\mathcal{Y} = \{y = g(x) : x \in \mathcal{X}\} \ .
\tag{2}
$$

Proof: The support of Y is determined by $g(x)$ and by the set of possible outcomes of X. Moreover, if $g(x)$ is strictly decreasing, then $g^{-1}(y)$ is also strictly decreasing. Therefore, the cumulative distribution function ($\to$ Definition I/1.4.8) of Y can be derived as follows:

1) If y is higher than the highest value ($\to$ Definition I/1.11.2) Y can take, then $\Pr(Y \leq y) = 1$, so

$$
F_Y(y) = 1, \quad \text{if} \quad y > \max(\mathcal{Y}) \ .
\tag{3}
$$

2) If y belongs to the support of Y, then $F_Y(y)$ can be derived as follows:

$$
\begin{aligned}
F_Y(y) &= \Pr(Y \leq y) \\
&= 1 - \Pr(Y > y) \\
&= 1 - \Pr(g(X) > y) \\
&= 1 - \Pr(X < g^{-1}(y)) \\
&= 1 - \Pr(X < g^{-1}(y)) - \Pr(X = g^{-1}(y)) + \Pr(X = g^{-1}(y)) \\
&= 1 - \left[\Pr(X < g^{-1}(y)) + \Pr(X = g^{-1}(y))\right] + \Pr(X = g^{-1}(y)) \\
&= 1 - \Pr(X \leq g^{-1}(y)) + \Pr(X = g^{-1}(y)) \\
&= 1 - F_X(g^{-1}(y)) + \Pr(X = g^{-1}(y)) \, .
\end{aligned}
\tag{4}
$$

3) If y is lower than the lowest value ($\rightarrow$ Definition I/1.11.1) Y can take, then $\Pr(Y \leq y) = 0$, so

$$
F_Y(y) = 0, \quad \text{if} \quad y < \min(\mathcal{Y}) \, .
\tag{5}
$$

Taking together (3), (4), (5), eventually proves (1).

1.4.11 Cumulative distribution function of discrete random variable

Theorem: Let X be a discrete ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) with possible values $\mathcal{X}$ and probability mass function ($\rightarrow$ Definition I/1.4.1) $f_X(x)$. Then, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of X is

$$
F_X(x) = \sum_{\substack{t \in \mathcal{X} \\ t \leq x}} f_X(t) \, .
\tag{1}
$$

Proof: The cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of a random variable ($\rightarrow$ Definition I/1.1.3) X is defined as the probability that X is smaller than x:

$$
F_X(x) = \Pr(X \leq x) \, .
\tag{2}
$$

The probability mass function ($\rightarrow$ Definition I/1.4.1) of a discrete ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) X returns the probability that X takes a particular value x:

$$
f_X(x) = \Pr(X = x) \, .
\tag{3}
$$

Taking these two definitions together, we have:

$$F_X(x) \overset{(2)}{=} \sum_{\substack{t \in \mathcal{X} \\ t \leq x}} \Pr(X = t)$$

$$\overset{(3)}{=} \sum_{\substack{t \in \mathcal{X} \\ t \leq x}} f_X(t) \ . \tag{4}$$

1.4.12 Cumulative distribution function of continuous random variable

Theorem: Let X be a continuous ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) with possible values $\mathcal{X}$ and probability density function ($\rightarrow$ Definition I/1.4.4) $f_X(x)$. Then, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of X is

$$F_X(x) = \int_{-\infty}^{x} f_X(t)\, \mathrm{d}t \ . \tag{1}$$

Proof: The cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of a random variable ($\rightarrow$ Definition I/1.1.3) X is defined as the probability that X is smaller than x:

$$F_X(x) = \Pr(X \leq x) \ . \tag{2}$$

The probability density function ($\rightarrow$ Definition I/1.4.4) of a continuous ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) X can be used to calculate the probability that X falls into a particular interval A:

$$\Pr(X \in A) = \int_A f_X(x)\, \mathrm{d}x \ . \tag{3}$$

Taking these two definitions together, we have:

$$F_X(x) \overset{(2)}{=} \Pr(X \in (-\infty, x])$$

$$\overset{(3)}{=} \int_{-\infty}^{x} f_X(t)\, \mathrm{d}t \ . \tag{4}$$

1.4.13 Probability integral transform

Theorem: Let X be a continuous ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) with invertible ($\rightarrow$ Definition I/1.4.17) cumulative distribution function ($\rightarrow$ Definition I/1.4.8) $F_X(x)$. Then, the random variable ($\rightarrow$ Definition I/1.1.3)

$$Y = F_X(X) \tag{1}$$

has a standard uniform distribution ($\rightarrow$ Definition "suni").

Proof: The cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of $Y = F_X(X)$ can be derived as

$$
\begin{aligned}
F_Y(y) &= \Pr(Y \leq y) \\
&= \Pr(F_X(X) \leq y) \\
&= \Pr(X \leq F_X^{-1}(y)) \\
&= F_X(F_X^{-1}(y)) \\
&= y
\end{aligned}
\tag{2}
$$

which is the cumulative distribution function of a continuous uniform distribution ($\rightarrow$ Proof II/3.1.3) with $a = 0$ and $b = 1$, i.e. the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of the standard uniform distribution ($\rightarrow$ Definition "suni") $\mathcal{U}(0, 1)$.

Sources:
- Wikipedia (2021): "Probability integral transform"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-04-07; URL: https://en.wikipedia.org/wiki/Probability_integral_transform#Proof.

Metadata: ID: P220 | shortcut: cdf-pit | author: JoramSoch | date: 2021-04-07, 08:47.

1.4.14 Inverse transformation method

Theorem: Let U be a continuous ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3) having a standard uniform distribution ($\rightarrow$ Definition "suni"). Then, the random variable ($\rightarrow$ Definition I/1.1.3)

$$X = F_X^{-1}(U) \tag{1}$$

has a probability distribution ($\rightarrow$ Definition I/1.3.1) characterized by the invertible ($\rightarrow$ Definition I/1.4.17) cumulative distribution function ($\rightarrow$ Definition I/1.4.8) $F_X(x)$.

Proof: The cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of the transformation $X = F_X^{-1}(U)$ can be derived as

$$
\begin{aligned}
&\Pr(X \leq x) \\
&= \Pr(F_X^{-1}(U) \leq x) \\
&= \Pr(U \leq F_X(x)) \\
&= F_X(x) \, ,
\end{aligned}
\tag{2}
$$

because the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of the standard uniform distribution ($\rightarrow$ Definition "suni") $\mathcal{U}(0,1)$ is

$$U \sim \mathcal{U}(0,1) \quad \Rightarrow \quad F_U(u) = \Pr(U \leq u) = u \ . \tag{3}$$

Sources:
- Wikipedia (2021): "Inverse transform sampling"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-04-07; URL: https://en.wikipedia.org/wiki/Inverse_transform_sampling#Proof_of_correctness.

Metadata: ID: P221 | shortcut: cdf-itm | author: JoramSoch | date: 2021-04-07, 08:47.

1.4.15   Distributional transformation

Theorem: Let X and Y be two continuous ($\rightarrow$ Definition I/1.1.7) random variables ($\rightarrow$ Definition I/1.1.3) with cumulative distribution function ($\rightarrow$ Definition I/1.4.8) $F_X(x)$ and invertible cumulative distribution function ($\rightarrow$ Definition I/1.4.8) $F_Y(y)$. Then, the random variable ($\rightarrow$ Definition I/1.1.3)

$$\tilde{X} = F_Y^{-1}(F_X(X)) \tag{1}$$

has the same probability distribution ($\rightarrow$ Definition I/1.3.1) as Y.

Proof: The cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of the transformation $\tilde{X} = F_Y^{-1}(F_X(X))$ can be derived as

$$
\begin{aligned}
F_{\tilde{X}}(y) &= \Pr\left(\tilde{X} \leq y\right) \\
&= \Pr\left(F_Y^{-1}(F_X(X)) \leq y\right) \\
&= \Pr\left(F_X(X) \leq F_Y(y)\right) \\
&= \Pr\left(X \leq F_X^{-1}(F_Y(y))\right) \\
&= F_X\left(F_X^{-1}(F_Y(y))\right) \\
&= F_Y(y)
\end{aligned}
\tag{2}
$$

which shows that $\tilde{X}$ and Y have the same cumulative distribution function ($\rightarrow$ Definition I/1.4.8) and are thus identically distributed ($\rightarrow$ Definition I/1.3.1).

1.4.17 Quantile function

Definition: Let X be a random variable ($\to$ Definition I/1.1.3) with the cumulative distribution function ($\to$ Definition I/1.4.8) (CDF) $F_X(x)$. Then, the function $Q_X(p) : [0, 1] \to \mathbb{R}$ which is the inverse CDF is the quantile function (QF) of X. More precisely, the QF is the function that, for a given quantile $p \in [0, 1]$, returns the smallest x for which $F_X(x) = p$:

$$Q_X(p) = \min \{x \in \mathbb{R} \,|\, F_X(x) = p\} \ . \tag{1}$$

Sources:
- Wikipedia (2020): "Probability density function"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-17; URL: https://en.wikipedia.org/wiki/Quantile_function#Definition.

Metadata: ID: D14 | shortcut: qf | author: JoramSoch | date: 2020-02-17, 22:18.

1.4.18 Quantile function in terms of cumulative distribution function

Theorem: Let X be a continuous ($\to$ Definition I/1.1.7) random variable ($\to$ Definition I/1.1.3) with the cumulative distribution function ($\to$ Definition I/1.4.8) $F_X(x)$. If the cumulative distribution function is strictly monotonically increasing, then the quantile function ($\to$ Definition I/1.4.17) is identical to the inverse of $F_X(x)$:

$$Q_X(p) = F_X^{-1}(x) \ . \tag{1}$$

Proof: The quantile function ($\to$ Definition I/1.4.17) $Q_X(p)$ is defined as the function that, for a given quantile $p \in [0, 1]$, returns the smallest x for which $F_X(x) = p$:

$$Q_X(p) = \min \{x \in \mathbb{R} \,|\, F_X(x) = p\} \ . \tag{2}$$

If $F_X(x)$ is continuous and strictly monotonically increasing, then there is exactly one x for which $F_X(x) = p$ and $F_X(x)$ is an invertible function, such that

$$Q_X(p) = F_X^{-1}(x) \ . \tag{3}$$

Sources:

- Wikipedia (2020): "Quantile function"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-11-12; URL: https://en.wikipedia.org/wiki/Quantile_function#Definition.

1.4.20 Moment-generating function of linear transformation

Theorem: Let X be an $n \times 1$ random vector ($\to$ Definition I/1.1.4) with the moment-generating function ($\to$ Definition I/1.4.19) $M_X(t)$. Then, the moment-generating function of the linear transformation $Y = AX + b$ is given by

$$M_Y(t) = \exp\left[t^\mathrm{T} b\right] \cdot M_X(At) \tag{1}$$

where A is an $m \times n$ matrix and b is an $m \times 1$ vector.

Proof: The moment-generating function of a random vector ($\to$ Definition I/1.4.19) X is

$$M_X(t) = \mathrm{E}\left(\exp\left[t^\mathrm{T} X\right]\right) \tag{2}$$

and therefore the moment-generating function of the random vector ($\to$ Definition I/1.1.4) Y is given by

$$
\begin{aligned}
M_Y(t) &= \mathrm{E}\left(\exp\left[t^\mathrm{T}(AX + b)\right]\right) \\
&= \mathrm{E}\left(\exp\left[t^\mathrm{T} AX\right] \cdot \exp\left[t^\mathrm{T} b\right]\right) \\
&= \exp\left[t^\mathrm{T} b\right] \cdot \mathrm{E}\left(\exp\left[(At)^\mathrm{T} X\right]\right) \\
&= \exp\left[t^\mathrm{T} b\right] \cdot M_X(At) .
\end{aligned}
\tag{3}
$$

1.4.21 Moment-generating function of linear combination

Theorem: Let $X_1, \ldots, X_n$ be n independent ($\to$ Definition I/1.2.6) random variables ($\to$ Definition I/1.1.3) with moment-generating functions ($\to$ Definition I/1.4.19) $M_{X_i}(t)$. Then, the moment-generating function of the linear combination $X = \sum_{i=1}^{n} a_i X_i$ is given by

$$M_X(t) = \prod_{i=1}^{n} M_{X_i}(a_i t) \tag{1}$$

where $a_1, \ldots, a_n$ are n real numbers.

Proof: The moment-generating function of a random variable ($\to$ Definition I/1.4.19) X_i is

$$M_{X_i}(t) = \mathrm{E}\left(\exp\left[t X_i\right]\right) \tag{2}$$

and therefore the moment-generating function of the linear combination X is given by

$$
\begin{aligned}
M_X(t) &= \mathrm{E}\left(\exp\left[t X\right]\right) \\
&= \mathrm{E}\left(\exp\left[t \sum_{i=1}^{n} a_i X_i\right]\right) \\
&= \mathrm{E}\left(\prod_{i=1}^{n} \exp\left[t\, a_i X_i\right]\right) \ .
\end{aligned}
\tag{3}
$$

Because the expected value is multiplicative for independent random variables ($\to$ Proof I/1.5.7), we have

$$
\begin{aligned}
M_X(t) &= \prod_{i=1}^{n} \mathrm{E}\left(\exp\left[(a_i t) X_i\right]\right) \\
&= \prod_{i=1}^{n} M_{X_i}(a_i t) \ .
\end{aligned}
\tag{4}
$$

1.4.22 Cumulant-generating function

Definition:
1) The cumulant-generating function of a random variable ($\to$ Definition I/1.1.3) $X \in \mathbb{R}$ is

$$K_X(t) = \log \mathrm{E}\left[e^{tX}\right], \quad t \in \mathbb{R} . \tag{1}$$

2) The cumulant-generating function of a random vector ($\to$ Definition I/1.1.4) $X \in \mathbb{R}^n$ is

$$K_X(t) = \log \mathrm{E}\left[e^{t^{\mathrm{T}}X}\right], \quad t \in \mathbb{R}^n . \tag{2}$$

Sources:
- Wikipedia (2020): "Cumulant"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-31; URL: https://en.wikipedia.org/wiki/Cumulant#Definition.

Metadata: ID: D68 | shortcut: cgf | author: JoramSoch | date: 2020-05-31, 23:46.

1.4.23 Probability-generating function

Definition:
1) If X is a discrete random variable ($\to$ Definition I/1.1.3) taking values in the non-negative integers $\{0, 1, \ldots\}$, then the probability-generating function of X is defined as

$$G_X(z) = \mathrm{E}\left[z^X\right] = \sum_{x=0}^{\infty} p(x)\, z^x \tag{1}$$

where $z \in \mathbb{C}$ and $p(x)$ is the probability mass function ($\to$ Definition I/1.4.1) of X.
2) If X is a discrete random vector ($\to$ Definition I/1.1.4) taking values in the n-dimensional integer lattice $x \in \{0, 1, \ldots\}^n$, then the probability-generating function of X is defined as

$$G_X(z) = \mathrm{E}\left[z_1^{X_1} \cdot \ldots \cdot z_n^{X_n}\right] = \sum_{x_1=0}^{\infty} \cdots \sum_{x_n=0}^{\infty} p(x_1, \ldots, x_n)\, z_1^{x_1} \cdot \ldots \cdot z_n^{x_n} \tag{2}$$

where $z \in \mathbb{C}^n$ and $p(x)$ is the probability mass function ($\to$ Definition I/1.4.1) of X.

Sources:
- Wikipedia (2020): "Probability-generating function"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-31; URL: https://en.wikipedia.org/wiki/Probability-generating_function#Definition.

1.5 Expected value

1.5.1 Definition

Definition:
1) The expected value (or, mean) of a discrete random variable ($\to$ Definition I/1.1.3) X with domain $\mathcal{X}$ is

$$\mathrm{E}(X) = \sum_{x \in \mathcal{X}} x \cdot f_X(x) \tag{1}$$

where $f_X(x)$ is the probability mass function ($\rightarrow$ Definition I/1.4.1) of X.

2) The expected value (or, mean) of a continuous random variable ($\rightarrow$ Definition I/1.1.3) X with domain $\mathcal{X}$ is

$$\mathrm{E}(X) = \int_{\mathcal{X}} x \cdot f_X(x)\, \mathrm{d}x \tag{2}$$

where $f_X(x)$ is the probability density function ($\rightarrow$ Definition I/1.4.4) of X.

Sources:
- Wikipedia (2020): "Expected value"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-13; URL: https://en.wikipedia.org/wiki/Expected_value#Definition.

Metadata: ID: D11 | shortcut: mean | author: JoramSoch | date: 2020-02-13, 19:38.

1.5.2 Sample mean

Definition: Let $x = \{x_1, \ldots, x_n\}$ be a sample ($\rightarrow$ Definition "samp") from a random variable ($\rightarrow$ Definition I/1.1.3) X. Then, the sample mean of x is denoted as $\bar{x}$ and is given by

$$\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i \;. \tag{1}$$

Sources:
- Wikipedia (2021): "Sample mean and covariance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-04-16; URL: https://en.wikipedia.org/wiki/Sample_mean_and_covariance#Definition_of_the_sample_mean.

Metadata: ID: D142 | shortcut: mean-samp | author: JoramSoch | date: 2021-04-16, 11:53.

1.5.3 Non-negative random variable

Theorem: Let X be a non-negative random variable ($\rightarrow$ Definition I/1.1.3). Then, the expected value ($\rightarrow$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = \int_{0}^{\infty} (1 - F_X(x))\, \mathrm{d}x \tag{1}$$

where $F_X(x)$ is the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of X.

Proof: Because the cumulative distribution function gives the probability of a random variable being smaller than a given value ($\rightarrow$ Definition I/1.4.8),

$$F_X(x) = \mathrm{Pr}(X \leq x) \;, \tag{2}$$

we have

$$1 - F_X(x) = \Pr(X > x) \,, \tag{3}$$

such that

$$\int_0^\infty (1 - F_X(x)) \, \mathrm{d}x = \int_0^\infty \Pr(X > x) \, \mathrm{d}x \tag{4}$$

which, using the probability density function ($\rightarrow$ Definition I/1.4.4) of X, can be rewritten as

$$
\begin{aligned}
\int_0^\infty (1 - F_X(x)) \, \mathrm{d}x &= \int_0^\infty \int_x^\infty f_X(z) \, \mathrm{d}z \, \mathrm{d}x \\
&= \int_0^\infty \int_0^z f_X(z) \, \mathrm{d}x \, \mathrm{d}z \\
&= \int_0^\infty f_X(z) \int_0^z 1 \, \mathrm{d}x \, \mathrm{d}z \\
&= \int_0^\infty [x]_0^z \cdot f_X(z) \, \mathrm{d}z \\
&= \int_0^\infty z \cdot f_X(z) \, \mathrm{d}z
\end{aligned} \tag{5}
$$

and by applying the definition of the expected value ($\rightarrow$ Definition I/1.5.1), we see that

$$\int_0^\infty (1 - F_X(x)) \, \mathrm{d}x = \int_0^\infty z \cdot f_X(z) \, \mathrm{d}z = \mathrm{E}(X) \tag{6}$$

which proves the identity given above.

Sources:
- Kemp, Graham (2014): "Expected value of a non-negative random variable"; in: *StackExchange Mathematics*, retrieved on 2020-05-18; URL: https://math.stackexchange.com/questions/958472/expected-value-of-a-non-negative-random-variable.

Metadata: ID: P103 | shortcut: mean-nnrvar | author: JoramSoch | date: 2020-05-18, 23:54.

1.5.4 Non-negativity

Theorem: If a random variable ($\rightarrow$ Definition I/1.1.3) is strictly non-negative, its expected value ($\rightarrow$ Definition I/1.5.1) is also non-negative, i.e.

$$\mathrm{E}(X) \geq 0, \quad \text{if} \quad X \geq 0 \,. \tag{1}$$

Proof:
1) If $X \geq 0$ is a discrete random variable, then, because the probability mass function ($\rightarrow$ Definition I/1.4.1) is always non-negative, all the addends in

$$\mathrm{E}(X) = \sum_{x \in \mathcal{X}} x \cdot f_X(x) \tag{2}$$

are non-negative, thus the entire sum must be non-negative.

2) If $X \geq 0$ is a continuous random variable, then, because the probability density function ($\rightarrow$ Definition I/1.4.4) is always non-negative, the integrand in

$$ \mathrm{E}(X) = \int_{\mathcal{X}} x \cdot f_X(x) \, \mathrm{d}x \tag{3} $$

is strictly non-negative, thus the term on the right-hand side is a Lebesgue integral, so that the result on the left-hand side must be non-negative.

Sources:
- Wikipedia (2020): "Expected value"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-13; URL: https://en.wikipedia.org/wiki/Expected_value#Basic_properties.

Metadata: ID: P52 | shortcut: mean-nonneg | author: JoramSoch | date: 2020-02-13, 20:14.

1.5.5 Linearity

Theorem: The expected value ($\rightarrow$ Definition I/1.5.1) is a linear operator, i.e.

$$ \begin{aligned} \mathrm{E}(X + Y) &= \mathrm{E}(X) + \mathrm{E}(Y) \\ \mathrm{E}(a\,X) &= a\,\mathrm{E}(X) \end{aligned} \tag{1} $$

for random variables ($\rightarrow$ Definition I/1.1.3) X and Y and a constant a.

Proof:
1) If X and Y are discrete random variables, the expected value ($\rightarrow$ Definition I/1.5.1) is

$$ \mathrm{E}(X) = \sum_{x \in \mathcal{X}} x \cdot f_X(x) \tag{2} $$

and the law of marginal probability ($\rightarrow$ Definition I/1.2.3) states that

$$ p(x) = \sum_{y \in \mathcal{Y}} p(x, y) \,. \tag{3} $$

Applying this, we have

$$ \begin{aligned} \mathrm{E}(X + Y) &= \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} (x + y) \cdot f_{X,Y}(x, y) \\ &= \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} x \cdot f_{X,Y}(x, y) + \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} y \cdot f_{X,Y}(x, y) \\ &= \sum_{x \in \mathcal{X}} x \sum_{y \in \mathcal{Y}} f_{X,Y}(x, y) + \sum_{y \in \mathcal{Y}} y \sum_{x \in \mathcal{X}} f_{X,Y}(x, y) \\ &\overset{(3)}{=} \sum_{x \in \mathcal{X}} x \cdot f_X(x) + \sum_{y \in \mathcal{Y}} y \cdot f_Y(y) \\ &\overset{(2)}{=} \mathrm{E}(X) + \mathrm{E}(Y) \end{aligned} \tag{4} $$

as well as

$$\mathrm{E}(a\,X) = \sum_{x \in \mathcal{X}} a\,x \cdot f_X(x)$$

$$= a \sum_{x \in \mathcal{X}} x \cdot f_X(x) \tag{5}$$

$$\overset{(2)}{=} a\,\mathrm{E}(X)\,.$$

2) If X and Y are continuous random variables, the expected value ($\to$ Definition I/1.5.1) is

$$\mathrm{E}(X) = \int_{\mathcal{X}} x \cdot f_X(x)\,\mathrm{d}x \tag{6}$$

and the law of marginal probability ($\to$ Definition I/1.2.3) states that

$$p(x) = \int_{\mathcal{Y}} p(x, y)\,\mathrm{d}y\,. \tag{7}$$

Applying this, we have

$$
\begin{aligned}
\mathrm{E}(X + Y) &= \int_{\mathcal{X}} \int_{\mathcal{Y}} (x + y) \cdot f_{X,Y}(x, y)\,\mathrm{d}y\,\mathrm{d}x \\
&= \int_{\mathcal{X}} \int_{\mathcal{Y}} x \cdot f_{X,Y}(x, y)\,\mathrm{d}y\,\mathrm{d}x + \int_{\mathcal{X}} \int_{\mathcal{Y}} y \cdot f_{X,Y}(x, y)\,\mathrm{d}y\,\mathrm{d}x \\
&= \int_{\mathcal{X}} x \int_{\mathcal{Y}} f_{X,Y}(x, y)\,\mathrm{d}y\,\mathrm{d}x + \int_{\mathcal{Y}} y \int_{\mathcal{X}} f_{X,Y}(x, y)\,\mathrm{d}x\,\mathrm{d}y \\
&\overset{(7)}{=} \int_{\mathcal{X}} x \cdot f_X(x)\,\mathrm{d}x + \int_{\mathcal{Y}} y \cdot f_Y(y)\,\mathrm{d}y \\
&\overset{(6)}{=} \mathrm{E}(X) + \mathrm{E}(Y)
\end{aligned}
\tag{8}
$$

as well as

$$
\begin{aligned}
\mathrm{E}(a\,X) &= \int_{\mathcal{X}} a\,x \cdot f_X(x)\,\mathrm{d}x \\
&= a \int_{\mathcal{X}} x \cdot f_X(x)\,\mathrm{d}x \\
&\overset{(6)}{=} a\,\mathrm{E}(X)\,.
\end{aligned}
\tag{9}
$$

Collectively, this shows that both requirements for linearity are fulfilled for the expected value, for discrete as well as for continuous random variables.

Metadata: ID: P53 | shortcut: mean-lin | author: JoramSoch | date: 2020-02-13, 21:08.

1.5.6 Monotonicity

Theorem: The expected value ($\rightarrow$ Definition I/1.5.1) is monotonic, i.e.

$$\mathrm{E}(X) \leq \mathrm{E}(Y), \quad \text{if} \quad X \leq Y \;. \tag{1}$$

Proof: Let $Z = Y - X$. Due to the linearity of the expected value ($\rightarrow$ Proof I/1.5.5), we have

$$\mathrm{E}(Z) = \mathrm{E}(Y - X) = \mathrm{E}(Y) - \mathrm{E}(X) \;. \tag{2}$$

With the non-negativity property of the expected value ($\rightarrow$ Proof I/1.5.4), it also holds that

$$Z \geq 0 \quad \Rightarrow \quad \mathrm{E}(Z) \geq 0 \;. \tag{3}$$

Together with (2), this yields

$$\mathrm{E}(Y) - \mathrm{E}(X) \geq 0 \;. \tag{4}$$

Sources:
- Wikipedia (2020): "Expected value"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-17; URL: https://en.wikipedia.org/wiki/Expected_value#Basic_properties.

Metadata: ID: P54 | shortcut: mean-mono | author: JoramSoch | date: 2020-02-17, 21:00.

1.5.7 (Non-)Multiplicativity

Theorem:
1) If two random variables ($\rightarrow$ Definition I/1.1.3) X and Y are independent ($\rightarrow$ Definition I/1.2.6), the expected value ($\rightarrow$ Definition I/1.5.1) is multiplicative, i.e.

$$\mathrm{E}(X\,Y) = \mathrm{E}(X)\,\mathrm{E}(Y) \;. \tag{1}$$

2) If two random variables ($\rightarrow$ Definition I/1.1.3) X and Y are dependent ($\rightarrow$ Definition I/1.2.6), the expected value ($\rightarrow$ Definition I/1.5.1) is not necessarily multiplicative, i.e. there exist X and Y such that

$$\mathrm{E}(X\,Y) \neq \mathrm{E}(X)\,\mathrm{E}(Y) \;. \tag{2}$$

Proof:
1) If X and Y are independent ($\rightarrow$ Definition I/1.2.6), it holds that

$$p(x, y) = p(x)\,p(y) \quad \text{for all} \quad x \in \mathcal{X}, y \in \mathcal{Y} \;. \tag{3}$$

Applying this to the expected value for discrete random variables ($\rightarrow$ Definition I/1.5.1), we have

$$\mathrm{E}(X\,Y) = \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} (x \cdot y) \cdot f_{X,Y}(x, y)$$

$$\overset{(3)}{=} \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} (x \cdot y) \cdot (f_X(x) \cdot f_Y(y))$$

$$= \sum_{x \in \mathcal{X}} x \cdot f_X(x) \sum_{y \in \mathcal{Y}} y \cdot f_Y(y) \qquad (4)$$

$$= \sum_{x \in \mathcal{X}} x \cdot f_X(x) \cdot \mathrm{E}(Y)$$

$$= \mathrm{E}(X)\,\mathrm{E}(Y)\ .$$

And applying it to the expected value for continuous random variables ($\to$ Definition I/1.5.1), we have

$$\mathrm{E}(X\,Y) = \int_{\mathcal{X}} \int_{\mathcal{Y}} (x \cdot y) \cdot f_{X,Y}(x, y)\,\mathrm{d}y\,\mathrm{d}x$$

$$\overset{(3)}{=} \int_{\mathcal{X}} \int_{\mathcal{Y}} (x \cdot y) \cdot (f_X(x) \cdot f_Y(y))\ \mathrm{d}y\,\mathrm{d}x$$

$$= \int_{\mathcal{X}} x \cdot f_X(x) \int_{\mathcal{Y}} y \cdot f_Y(y)\,\mathrm{d}y\,\mathrm{d}x \qquad (5)$$

$$= \int_{\mathcal{X}} x \cdot f_X(x) \cdot \mathrm{E}(Y)\,\mathrm{d}x$$

$$= \mathrm{E}(X)\,\mathrm{E}(Y)\ .$$

2) Let X and Y be Bernoulli random variables ($\to$ Definition II/1.2.1) with the following joint probability ($\to$ Definition I/1.2.2) mass function ($\to$ Definition I/1.4.1)

$$\begin{aligned} p(X = 0, Y = 0) &= 1/2 \\ p(X = 0, Y = 1) &= 0 \\ p(X = 1, Y = 0) &= 0 \\ p(X = 1, Y = 1) &= 1/2 \end{aligned} \qquad (6)$$

and thus, the following marginal probabilities:

$$\begin{aligned} p(X = 0) &= p(X = 1) = 1/2 \\ p(Y = 0) &= p(Y = 1) = 1/2\ . \end{aligned} \qquad (7)$$

Then, X and Y are dependent, because

$$p(X = 0, Y = 1) \overset{(6)}{=} 0 \neq \frac{1}{2} \cdot \frac{1}{2} \overset{(7)}{=} p(X = 0)\,p(Y = 1)\ , \qquad (8)$$

and the expected value of their product is

$$\mathrm{E}(X\,Y) = \sum_{x\in\{0,1\}}\sum_{y\in\{0,1\}}(x\cdot y)\cdot p(x,y)$$
$$= (1\cdot 1)\cdot p(X=1,Y=1) \tag{9}$$
$$\overset{(6)}{=} \frac{1}{2}$$

while the product of their expected values is

$$\mathrm{E}(X)\,\mathrm{E}(Y) = \left(\sum_{x\in\{0,1\}}x\cdot p(x)\right)\cdot\left(\sum_{y\in\{0,1\}}y\cdot p(y)\right)$$
$$= (1\cdot p(X=1))\cdot(1\cdot p(Y=1)) \tag{10}$$
$$\overset{(7)}{=} \frac{1}{4}$$

and thus,

$$\mathrm{E}(X\,Y) \neq \mathrm{E}(X)\,\mathrm{E}(Y)\,. \tag{11}$$

1.5.8 Expectation of a quadratic form

Theorem: Let X be an $n \times 1$ random vector ($\to$ Definition I/1.1.4) with mean ($\to$ Definition I/1.5.1) μ and covariance ($\to$ Definition I/1.7.1) Σ and let A be a symmetric $n \times n$ matrix. Then, the expectation of the quadratic form $X^{\mathrm{T}}AX$ is

$$\mathrm{E}\left[X^{\mathrm{T}}AX\right] = \mu^{\mathrm{T}}A\mu + \mathrm{tr}(A\Sigma)\,. \tag{1}$$

Proof: Note that $X^{\mathrm{T}}AX$ is a 1×1 matrix. We can therefore write

$$\mathrm{E}\left[X^{\mathrm{T}}AX\right] = \mathrm{E}\left[\mathrm{tr}\left(X^{\mathrm{T}}AX\right)\right]\,. \tag{2}$$

Using the trace property $\mathrm{tr}(ABC) = \mathrm{tr}(BCA)$, this becomes

$$\mathrm{E}\left[X^{\mathrm{T}}AX\right] = \mathrm{E}\left[\mathrm{tr}\left(AXX^{\mathrm{T}}\right)\right]\,. \tag{3}$$

Because mean and trace are linear operators ($\to$ Proof I/1.5.5), we have

$$\mathrm{E}\left[X^{\mathrm{T}}AX\right] = \mathrm{tr}\left(A\,\mathrm{E}\left[XX^{\mathrm{T}}\right]\right)\,. \tag{4}$$

Note that the covariance matrix can be partitioned into expected values ($\to$ Proof I/1.7.7)

$$\text{Cov}(X, X) = \text{E}(XX^{\text{T}}) - \text{E}(X)\text{E}(X)^{\text{T}} , \tag{5}$$

such that the expected value of the quadratic form becomes

$$\text{E}\left[X^{\text{T}}AX\right] = \text{tr}\left(A\left[\text{Cov}(X, X) + \text{E}(X)\text{E}(X)^{\text{T}}\right]\right) . \tag{6}$$

Finally, applying mean and covariance of X, we have

$$\begin{aligned}
\text{E}\left[X^{\text{T}}AX\right] &= \text{tr}\left(A\left[\Sigma + \mu\mu^{\text{T}}\right]\right) \\
&= \text{tr}\left(A\Sigma + A\mu\mu^{\text{T}}\right) \\
&= \text{tr}(A\Sigma) + \text{tr}(A\mu\mu^{\text{T}}) \\
&= \text{tr}(A\Sigma) + \text{tr}(\mu^{\text{T}}A\mu) \\
&= \mu^{\text{T}}A\mu + \text{tr}(A\Sigma) .
\end{aligned} \tag{7}$$

1.5.9   Law of the unconscious statistician

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) and let $Y = g(X)$ be a function of this random variable.
1) If X is a discrete random variable with possible outcomes $\mathcal{X}$ and probability mass function ($\rightarrow$ Definition I/1.4.1) $f_X(x)$, the expected value ($\rightarrow$ Definition I/1.5.1) of $g(X)$ is

$$\text{E}[g(X)] = \sum_{x \in \mathcal{X}} g(x)f_X(x) . \tag{1}$$

2) If X is a continuous random variable with possible outcomes $\mathcal{X}$ and probability density function ($\rightarrow$ Definition I/1.4.4) $f_X(x)$, the expected value ($\rightarrow$ Definition I/1.5.1) of $g(X)$ is

$$\text{E}[g(X)] = \int_{\mathcal{X}} g(x)f_X(x)\,\text{d}x . \tag{2}$$

Proof: Suppose that g is differentiable and that its inverse g^{-1} is monotonic.
1) The expected value ($\rightarrow$ Definition I/1.5.1) of $Y = g(X)$ is defined as

$$E[Y] = \sum_{y \in \mathcal{Y}} y \, f_Y(y) \, . \tag{3}$$

Writing the probability mass function $f_Y(y)$ in terms of $y = g(x)$, we have:

$$
\begin{aligned}
E[g(X)] &= \sum_{y \in \mathcal{Y}} y \Pr(g(x) = y) \\
&= \sum_{y \in \mathcal{Y}} y \Pr(x = g^{-1}(y)) \\
&= \sum_{y \in \mathcal{Y}} y \sum_{x = g^{-1}(y)} f_X(x) \\
&= \sum_{y \in \mathcal{Y}} \sum_{x = g^{-1}(y)} y f_X(x) \\
&= \sum_{y \in \mathcal{Y}} \sum_{x = g^{-1}(y)} g(x) f_X(x) \, .
\end{aligned}
\tag{4}
$$

Finally, noting that "for all y, then for all $x = g^{-1}(y)$" is equivalent to "for all x" if g^{-1} is a monotonic function, we can conclude that

$$E[g(X)] = \sum_{x \in \mathcal{X}} g(x) f_X(x) \, . \tag{5}$$

2) Let $y = g(x)$. The derivative of an inverse function is

$$\frac{\mathrm{d}}{\mathrm{d}y}(g^{-1}(y)) = \frac{1}{g'(g^{-1}(y))} \tag{6}$$

Because $x = g^{-1}(y)$, this can be rearranged into

$$\mathrm{d}x = \frac{1}{g'(g^{-1}(y))} \, \mathrm{d}y \tag{7}$$

and subsitituing (7) into (2), we get

$$\int_{\mathcal{X}} g(x) f_X(x) \, \mathrm{d}x = \int_{\mathcal{Y}} y \, f_X(g^{-1}(y)) \, \frac{1}{g'(g^{-1}(y))} \, \mathrm{d}y \, . \tag{8}$$

Considering the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of Y, one can deduce:

$$
\begin{aligned}
F_Y(y) &= \Pr(Y \leq y) \\
&= \Pr(g(X) \leq y) \\
&= \Pr(X \leq g^{-1}(y)) \\
&= F_X(g^{-1}(y)) \, .
\end{aligned}
\tag{9}
$$

Differentiating to get the probability density function ($\rightarrow$ Definition I/1.4.4) of Y, the result is:

$$
\begin{aligned}
f_Y(y) &= \frac{\mathrm{d}}{\mathrm{d}y} F_Y(y) \\
&\overset{(9)}{=} \frac{\mathrm{d}}{\mathrm{d}y} F_X(g^{-1}(y)) \\
&= f_X(g^{-1}(y)) \frac{\mathrm{d}}{\mathrm{d}y}(g^{-1}(y)) \\
&\overset{(6)}{=} f_X(g^{-1}(y)) \frac{1}{g'(g^{-1}(y))} \; .
\end{aligned}
\tag{10}
$$

Finally, substituing (10) into (8), we have:

$$
\int_{\mathcal{X}} g(x) f_X(x) \, \mathrm{d}x = \int_{\mathcal{Y}} y \, f_Y(y) \, \mathrm{d}y = \mathrm{E}[Y] = \mathrm{E}[g(X)] \; .
\tag{11}
$$

1.6   Variance

1.6.1   Definition

Definition: The variance of a random variable ($\rightarrow$ Definition I/1.1.3) X is defined as the expected value ($\rightarrow$ Definition I/1.5.1) of the squared deviation from its expected value ($\rightarrow$ Definition I/1.5.1):

$$
\mathrm{Var}(X) = \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] \; .
\tag{1}
$$

Sources:
- Wikipedia (2020): "Variance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-13; URL: https://en.wikipedia.org/wiki/Variance#Definition.

Metadata: ID: D12 | shortcut: var | author: JoramSoch | date: 2020-02-13, 19:55.

1.6.2   Sample variance

Definition: Let $x = \{x_1, \ldots, x_n\}$ be a sample ($\rightarrow$ Definition "samp") from a random variable ($\rightarrow$ Definition I/1.1.3) X. Then, the sample variance of x is given by

$$
\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^2
\tag{1}
$$

and the unbiased sample variance of x is given by

$$s^2 = \frac{1}{n-1} \sum_{i=1}^{n} (x_i - \bar{x})^2 \tag{2}$$

where $\bar{x}$ is the sample mean ($\rightarrow$ Definition I/1.5.2).

Sources:
- Wikipedia (2021): "Variance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-04-16; URL: https://en.wikipedia.org/wiki/Variance#Sample_variance.

Metadata: ID: D143 | shortcut: var-samp | author: JoramSoch | date: 2021-04-16, 12:04.

1.6.3 Partition into expected values

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3). Then, the variance ($\rightarrow$ Definition I/1.6.1) of X is equal to the mean ($\rightarrow$ Definition I/1.5.1) of the square of X minus the square of the mean ($\rightarrow$ Definition I/1.5.1) of X:

$$\mathrm{Var}(X) = \mathrm{E}(X^2) - \mathrm{E}(X)^2 \ . \tag{1}$$

Proof: The variance ($\rightarrow$ Definition I/1.6.1) of X is defined as

$$\mathrm{Var}(X) = \mathrm{E}\left[(X - \mathrm{E}[X])^2\right] \tag{2}$$

which, due to the linearity of the expected value ($\rightarrow$ Proof I/1.5.5), can be rewritten as

$$
\begin{aligned}
\mathrm{Var}(X) &= \mathrm{E}\left[(X - \mathrm{E}[X])^2\right] \\
&= \mathrm{E}\left[X^2 - 2X\,\mathrm{E}(X) + \mathrm{E}(X)^2\right] \\
&= \mathrm{E}(X^2) - 2\,\mathrm{E}(X)\,\mathrm{E}(X) + \mathrm{E}(X)^2 \\
&= \mathrm{E}(X^2) - \mathrm{E}(X)^2 \ .
\end{aligned}
\tag{3}
$$

Sources:
- Wikipedia (2020): "Variance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-19; URL: https://en.wikipedia.org/wiki/Variance#Definition.

Metadata: ID: P104 | shortcut: var-mean | author: JoramSoch | date: 2020-05-19, 00:17.

1.6.4 Non-negativity

Theorem: The variance ($\rightarrow$ Definition I/1.6.1) is always non-negative, i.e.

$$\mathrm{Var}(X) \geq 0 \ . \tag{1}$$

Proof: The variance ($\rightarrow$ Definition I/1.6.1) of a random variable ($\rightarrow$ Definition I/1.1.3) is defined as

$$\mathrm{Var}(X) = \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] \ . \tag{2}$$

1) If X is a discrete random variable ($\rightarrow$ Definition I/1.1.3), then, because squares and probabilities are stricly non-negative, all the addends in

$$\text{Var}(X) = \sum_{x \in \mathcal{X}} (x - \text{E}(X))^2 \cdot f_X(x) \tag{3}$$

are also non-negative, thus the entire sum must be non-negative.

2) If X is a continuous random variable ($\rightarrow$ Definition I/1.1.3), then, because squares and probability densities are strictly non-negative, the integrand in

$$\text{Var}(X) = \int_{\mathcal{X}} (x - \text{E}(X))^2 \cdot f_X(x) \, \text{d}x \tag{4}$$

is always non-negative, thus the term on the right-hand side is a Lebesgue integral, so that the result on the left-hand side must be non-negative.

Sources:
- Wikipedia (2020): "Variance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-06-06; URL: https://en.wikipedia.org/wiki/Variance#Basic_properties.

Metadata: ID: P123 | shortcut: var-nonneg | author: JoramSoch | date: 2020-06-06, 07:29.

1.6.5   Variance of a constant

Theorem: The variance ($\rightarrow$ Definition I/1.6.1) of a constant ($\rightarrow$ Definition I/1.1.6) is zero

$$a = \text{const.} \quad \Rightarrow \quad \text{Var}(a) = 0 \tag{1}$$

and if the variance ($\rightarrow$ Definition I/1.6.1) of X is zero, then X is a constant ($\rightarrow$ Definition I/1.1.6)

$$\text{Var}(X) = 0 \quad \Rightarrow \quad X = \text{const.} \, . \tag{2}$$

Proof:
1) A constant ($\rightarrow$ Definition I/1.1.6) is defined as a quantity that always has the same value. Thus, if understood as a random variable ($\rightarrow$ Definition I/1.1.3), the expected value ($\rightarrow$ Definition I/1.5.1) of a constant is equal to itself:

$$\text{E}(a) = a \, . \tag{3}$$

Plugged into the formula of the variance ($\rightarrow$ Definition I/1.6.1), we have

$$\begin{aligned}
\text{Var}(a) &= \text{E}\left[(a - \text{E}(a))^2\right] \\
&= \text{E}\left[(a - a)^2\right] \\
&= \text{E}(0) \, .
\end{aligned} \tag{4}$$

Applied to the formula of the expected value ($\rightarrow$ Definition I/1.5.1), this gives

$$\text{E}(0) = \sum_{x=0} x \cdot f_X(x) = 0 \cdot 1 = 0 \, . \tag{5}$$

Together, (4) and (5) imply (1).

2) The variance ($\to$ Definition I/1.6.1) is defined as

$$\mathrm{Var}(X) = \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] . \tag{6}$$

Because $(X - \mathrm{E}(X))^2$ is strictly non-negative ($\to$ Proof I/1.5.4), the only way for the variance to become zero is, if the squared deviation is always zero:

$$(X - \mathrm{E}(X))^2 = 0 . \tag{7}$$

Thus, in turn, requires that X is equal to its expected value ($\to$ Definition I/1.5.1)

$$X = \mathrm{E}(X) \tag{8}$$

which can only be the case, if X always has the same value ($\to$ Definition I/1.1.6):

$$X = \mathrm{const.} \tag{9}$$

Sources:
- Wikipedia (2020): "Variance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-06-27; URL: https://en.wikipedia.org/wiki/Variance#Basic_properties.

Metadata: ID: P124 | shortcut: var-const | author: JoramSoch | date: 2020-06-27, 06:44.

1.6.6 Invariance under addition

Theorem: The variance ($\to$ Definition I/1.6.1) is invariant under addition of a constant ($\to$ Definition I/1.1.6):

$$\mathrm{Var}(X + a) = \mathrm{Var}(X) \tag{1}$$

Proof: The variance ($\to$ Definition I/1.6.1) is defined in terms of the expected value ($\to$ Definition I/1.5.1) as

$$\mathrm{Var}(X) = \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] . \tag{2}$$

Using this and the linearity of the expected value ($\to$ Proof I/1.5.5), we can derive (1) as follows:

$$\begin{aligned}
\mathrm{Var}(X + a) &\overset{(2)}{=} \mathrm{E}\left[((X + a) - \mathrm{E}(X + a))^2\right] \\
&= \mathrm{E}\left[(X + a - \mathrm{E}(X) - a)^2\right] \\
&= \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] \\
&\overset{(2)}{=} \mathrm{Var}(X) .
\end{aligned} \tag{3}$$

Sources:
- Wikipedia (2020): "Variance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-07-07; URL: https://en.wikipedia.org/wiki/Variance#Basic_properties.

1.6.7   Scaling upon multiplication

Theorem: The variance ($\to$ Definition I/1.6.1) scales upon multiplication with a constant ($\to$ Definition I/1.1.6):

$$\mathrm{Var}(aX) = a^2 \, \mathrm{Var}(X) \tag{1}$$

Proof: The variance ($\to$ Definition I/1.6.1) is defined in terms of the expected value ($\to$ Definition I/1.5.1) as

$$\mathrm{Var}(X) = \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] \, . \tag{2}$$

Using this and the linearity of the expected value ($\to$ Proof I/1.5.5), we can derive (1) as follows:

$$
\begin{aligned}
\mathrm{Var}(aX) &\overset{(2)}{=} \mathrm{E}\left[((aX) - \mathrm{E}(aX))^2\right] \\
&= \mathrm{E}\left[(aX - a\mathrm{E}(X))^2\right] \\
&= \mathrm{E}\left[(a[X - \mathrm{E}(X)])^2\right] \\
&= \mathrm{E}\left[a^2(X - \mathrm{E}(X))^2\right] \\
&= a^2 \, \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] \\
&\overset{(2)}{=} a^2 \, \mathrm{Var}(X) \, .
\end{aligned}
\tag{3}
$$

Sources:
- Wikipedia (2020): "Variance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-07-07; URL: https://en.wikipedia.org/wiki/Variance#Basic_properties.

1.6.8   Variance of a sum

Theorem: The variance ($\to$ Definition I/1.6.1) of the sum of two random variables ($\to$ Definition I/1.1.3) equals the sum of the variances of those random variables, plus two times their covariance ($\to$ Definition I/1.7.1):

$$\mathrm{Var}(X + Y) = \mathrm{Var}(X) + \mathrm{Var}(Y) + 2 \, \mathrm{Cov}(X, Y) \, . \tag{1}$$

Proof: The variance ($\to$ Definition I/1.6.1) is defined in terms of the expected value ($\to$ Definition I/1.5.1) as

$$\mathrm{Var}(X) = \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] \, . \tag{2}$$

Using this and the linearity of the expected value ($\to$ Proof I/1.5.5), we can derive (1) as follows:

$$\mathrm{Var}(X+Y) \overset{(2)}{=} \mathrm{E}\left[((X+Y) - \mathrm{E}(X+Y))^2\right]$$
$$= \mathrm{E}\left[([X - \mathrm{E}(X)] + [Y - \mathrm{E}(Y)])^2\right]$$
$$= \mathrm{E}\left[(X - \mathrm{E}(X))^2 + (Y - \mathrm{E}(Y))^2 + 2(X - \mathrm{E}(X))(Y - \mathrm{E}(Y))\right] \qquad (3)$$
$$= \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] + \mathrm{E}\left[(Y - \mathrm{E}(Y))^2\right] + \mathrm{E}\left[2(X - \mathrm{E}(X))(Y - \mathrm{E}(Y))\right]$$
$$\overset{(2)}{=} \mathrm{Var}(X) + \mathrm{Var}(Y) + 2\,\mathrm{Cov}(X,Y) \ .$$

Sources:
- Wikipedia (2020): "Variance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-07-07; URL: https://en.wikipedia.org/wiki/Variance#Basic_properties.

1.6.9 Variance of linear combination

Theorem: The variance ($\rightarrow$ Definition I/1.6.1) of the linear combination of two random variables ($\rightarrow$ Definition I/1.1.3) is a function of the variances as well as the covariance ($\rightarrow$ Definition I/1.7.1) of those random variables:

$$\mathrm{Var}(aX + bY) = a^2\,\mathrm{Var}(X) + b^2\,\mathrm{Var}(Y) + 2ab\,\mathrm{Cov}(X,Y) \ . \qquad (1)$$

Proof: The variance ($\rightarrow$ Definition I/1.6.1) is defined in terms of the expected value ($\rightarrow$ Definition I/1.5.1) as

$$\mathrm{Var}(X) = \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] \ . \qquad (2)$$

Using this and the linearity of the expected value ($\rightarrow$ Proof I/1.5.5), we can derive (1) as follows:

$$\mathrm{Var}(aX + bY) \overset{(2)}{=} \mathrm{E}\left[((aX+bY) - \mathrm{E}(aX+bY))^2\right]$$
$$= \mathrm{E}\left[(a[X - \mathrm{E}(X)] + b[Y - \mathrm{E}(Y)])^2\right]$$
$$= \mathrm{E}\left[a^2(X - \mathrm{E}(X))^2 + b^2(Y - \mathrm{E}(Y))^2 + 2ab(X - \mathrm{E}(X))(Y - \mathrm{E}(Y))\right] \qquad (3)$$
$$= \mathrm{E}\left[a^2(X - \mathrm{E}(X))^2\right] + \mathrm{E}\left[b^2(Y - \mathrm{E}(Y))^2\right] + \mathrm{E}\left[2ab(X - \mathrm{E}(X))(Y - \mathrm{E}(Y))\right]$$
$$\overset{(2)}{=} a^2\,\mathrm{Var}(X) + b^2\,\mathrm{Var}(Y) + 2ab\,\mathrm{Cov}(X,Y) \ .$$

Sources:
- Wikipedia (2020): "Variance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-07-07; URL: https://en.wikipedia.org/wiki/Variance#Basic_properties.

1.6.10   Additivity under independence

Theorem: The variance ($\to$ Definition I/1.6.1) is additive for independent ($\to$ Definition I/1.2.6) random variables ($\to$ Definition I/1.1.3):

$$p(X, Y) = p(X)\, p(Y) \quad \Rightarrow \quad \mathrm{Var}(X + Y) = \mathrm{Var}(X) + \mathrm{Var}(Y) \,. \tag{1}$$

Proof: The variance of the sum of two random variables ($\to$ Proof I/1.6.8) is given by

$$\mathrm{Var}(X + Y) = \mathrm{Var}(X) + \mathrm{Var}(Y) + 2\,\mathrm{Cov}(X, Y) \,. \tag{2}$$

The covariance of independent random variables ($\to$ Proof I/1.7.4) is zero:

$$p(X, Y) = p(X)\, p(Y) \quad \Rightarrow \quad \mathrm{Cov}(X, Y) = 0 \,. \tag{3}$$

Combining (2) and (3), we have:

$$\mathrm{Var}(X + Y) = \mathrm{Var}(X) + \mathrm{Var}(Y) \,. \tag{4}$$

Sources:

1.7   Covariance

1.7.1   Definition

Definition: The covariance of two random variables ($\to$ Definition I/1.1.3) X and Y is defined as the expected value ($\to$ Definition I/1.5.1) of the product of their deviations from their individual expected values ($\to$ Definition I/1.5.1):

$$\mathrm{Cov}(X, Y) = \mathrm{E}\left[(X - \mathrm{E}[X])(Y - \mathrm{E}[Y])\right] \,. \tag{1}$$

Sources:
- Wikipedia (2020): "Covariance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-06; URL: https://en.wikipedia.org/wiki/Covariance#Definition.

Metadata: ID: D70 | shortcut: cov | author: JoramSoch | date: 2020-06-02, 20:20.

1.7.2 Sample covariance

Definition: Let $x = \{x_1, \ldots, x_n\}$ be a sample ($\rightarrow$ Definition "samp") from a random vector ($\rightarrow$ Definition I/1.1.4) $X \in \mathbb{R}^{n \times 1}$. Then, the sample covariance matrix of x is given by

$$\hat{\Sigma} = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})(x_i - \bar{x})^{\mathrm{T}} \tag{1}$$

and the unbiased sample variance matrix of x is given by

$$S = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})(x_i - \bar{x})^{\mathrm{T}} \tag{2}$$

where $\bar{x}$ is the sample mean ($\rightarrow$ Definition I/1.5.2).

Sources:
- Wikipedia (2021): "Sample mean and covariance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-04-21; URL: https://en.wikipedia.org/wiki/Sample_mean_and_covariance#Definition_of_sample_covariance.

Metadata: ID: D144 | shortcut: cov-samp | author: JoramSoch | date: 2021-04-21, 06:53.

1.7.3 Partition into expected values

Theorem: Let X and Y be random variables ($\rightarrow$ Definition I/1.1.3). Then, the covariance ($\rightarrow$ Definition I/1.7.1) of X and Y is equal to the mean ($\rightarrow$ Definition I/1.5.1) of the product of X and Y minus the product of the means ($\rightarrow$ Definition I/1.5.1) of X and Y:

$$\mathrm{Cov}(X, Y) = \mathrm{E}(XY) - \mathrm{E}(X)\mathrm{E}(Y) \, . \tag{1}$$

Proof: The covariance ($\rightarrow$ Definition I/1.7.1) of X and Y is defined as

$$\mathrm{Cov}(X, Y) = \mathrm{E}\left[(X - \mathrm{E}[X])(Y - \mathrm{E}[Y])\right] \, . \tag{2}$$

which, due to the linearity of the expected value ($\rightarrow$ Proof I/1.5.5), can be rewritten as

$$\begin{aligned}
\mathrm{Cov}(X, Y) &= \mathrm{E}\left[(X - \mathrm{E}[X])(Y - \mathrm{E}[Y])\right] \\
&= \mathrm{E}\left[XY - X\,\mathrm{E}(Y) - \mathrm{E}(X)\,Y + \mathrm{E}(X)\mathrm{E}(Y)\right] \\
&= \mathrm{E}(XY) - \mathrm{E}(X)\mathrm{E}(Y) - \mathrm{E}(X)\mathrm{E}(Y) + \mathrm{E}(X)\mathrm{E}(Y) \\
&= \mathrm{E}(XY) - \mathrm{E}(X)\mathrm{E}(Y) \, .
\end{aligned} \tag{3}$$

Sources:

- Wikipedia (2020): "Covariance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-06-02; URL: https://en.wikipedia.org/wiki/Covariance#Definition.

Metadata: ID: P118 | shortcut: cov-mean | author: JoramSoch | date: 2020-06-02, 20:50.

1.7.4 Covariance under independence

Theorem: Let X and Y be independent ($\to$ Definition I/1.2.6) random variables ($\to$ Definition I/1.1.3). Then, the covariance ($\to$ Definition I/1.7.1) of X and Y is zero:

$$X, Y \text{ independent} \quad \Rightarrow \quad \mathrm{Cov}(X, Y) = 0 \; . \tag{1}$$

Proof: The covariance can be expressed in terms of expected values ($\to$ Proof I/1.7.3) as

$$\mathrm{Cov}(X, Y) = \mathrm{E}(X\,Y) - \mathrm{E}(X)\,\mathrm{E}(Y) \; . \tag{2}$$

For independent random variables, the expected value of the product is equal to the product of the expected values ($\to$ Proof I/1.5.7):

$$\mathrm{E}(X\,Y) = \mathrm{E}(X)\,\mathrm{E}(Y) \; . \tag{3}$$

Taking (2) and (3) together, we have

$$\begin{aligned}
\mathrm{Cov}(X, Y) &\overset{(2)}{=} \mathrm{E}(X\,Y) - \mathrm{E}(X)\,\mathrm{E}(Y) \\
&\overset{(3)}{=} \mathrm{E}(X)\,\mathrm{E}(Y) - \mathrm{E}(X)\,\mathrm{E}(Y) \\
&= 0 \; .
\end{aligned} \tag{4}$$

Sources:
- Wikipedia (2020): "Covariance"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-09-03; URL: https://en.wikipedia.org/wiki/Covariance#Uncorrelatedness_and_independence.

Metadata: ID: P158 | shortcut: cov-ind | author: JoramSoch | date: 2020-09-03, 06:05.

1.7.5 Relationship to correlation

Theorem: Let X and Y be random variables ($\to$ Definition I/1.1.3). Then, the covariance ($\to$ Definition I/1.7.1) of X and Y is equal to the product of their correlation ($\to$ Definition I/1.8.1) and the standard deviations ($\to$ Definition I/1.10.1) of X and Y:

$$\mathrm{Cov}(X, Y) = \sigma_X \, \mathrm{Corr}(X, Y) \, \sigma_Y \; . \tag{1}$$

Proof: The correlation ($\to$ Definition I/1.8.1) of X and Y is defined as

$$\mathrm{Corr}(X, Y) = \frac{\mathrm{Cov}(X, Y)}{\sigma_X \sigma_Y} \; . \tag{2}$$

which can be rearranged for the covariance ($\to$ Definition I/1.7.1) to give

$$\mathrm{Cov}(X, Y) = \sigma_X \, \mathrm{Corr}(X, Y) \, \sigma_Y \tag{3}$$

1.7.6 Covariance matrix

Definition: Let $X = [X_1, \ldots, X_n]^\mathrm{T}$ be a random vector ($\rightarrow$ Definition I/1.1.4). Then, the covariance matrix of X is defined as the $n \times n$ matrix in which the entry (i, j) is the covariance ($\rightarrow$ Definition I/1.7.1) of X_i and X_j:

$$\Sigma_{XX} = \begin{bmatrix} \mathrm{Cov}(X_1, X_1) & \ldots & \mathrm{Cov}(X_1, X_n) \\ \vdots & \ddots & \vdots \\ \mathrm{Cov}(X_n, X_1) & \ldots & \mathrm{Cov}(X_n, X_n) \end{bmatrix} = \begin{bmatrix} \mathrm{E}\left[(X_1 - \mathrm{E}[X_1])(X_1 - \mathrm{E}[X_1])\right] & \ldots & \mathrm{E}\left[(X_1 - \mathrm{E}[X_1])(X_n - \mathrm{E} \\ \vdots & \ddots & \vdots \\ \mathrm{E}\left[(X_n - \mathrm{E}[X_n])(X_1 - \mathrm{E}[X_1])\right] & \ldots & \mathrm{E}\left[(X_n - \mathrm{E}[X_n])(X_n - \mathrm{E} \end{bmatrix} \tag{1}$$

Sources:
- Wikipedia (2020): "Covariance matrix"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-06-06; URL: https://en.wikipedia.org/wiki/Covariance_matrix#Definition.

1.7.7 Covariance matrix and expected values

Theorem: Let X be a random vector ($\rightarrow$ Definition I/1.1.4). Then, the covariance matrix ($\rightarrow$ Definition I/1.7.6) of X is equal to the mean ($\rightarrow$ Definition I/1.5.1) of the outer product of X with itself minus the outer product of the mean ($\rightarrow$ Definition I/1.5.1) of X with itself:

$$\Sigma_{XX} = \mathrm{E}(XX^\mathrm{T}) - \mathrm{E}(X)\mathrm{E}(X)^\mathrm{T} . \tag{1}$$

Proof: The covariance matrix ($\rightarrow$ Definition I/1.7.6) of X is defined as

$$\Sigma_{XX} = \begin{bmatrix} \mathrm{E}\left[(X_1 - \mathrm{E}[X_1])(X_1 - \mathrm{E}[X_1])\right] & \ldots & \mathrm{E}\left[(X_1 - \mathrm{E}[X_1])(X_n - \mathrm{E}[X_n])\right] \\ \vdots & \ddots & \vdots \\ \mathrm{E}\left[(X_n - \mathrm{E}[X_n])(X_1 - \mathrm{E}[X_1])\right] & \ldots & \mathrm{E}\left[(X_n - \mathrm{E}[X_n])(X_n - \mathrm{E}[X_n])\right] \end{bmatrix} \tag{2}$$

which can also be expressed using matrix multiplication as

$$\Sigma_{XX} = \mathrm{E}\left[(X - \mathrm{E}[X])(X - \mathrm{E}[X])^\mathrm{T}\right] \tag{3}$$

Due to the linearity of the expected value ($\rightarrow$ Proof I/1.5.5), this can be rewritten as

$$
\begin{aligned}
\Sigma_{XX} &= \mathrm{E}\left[(X - \mathrm{E}[X])(X - \mathrm{E}[X])^{\mathrm{T}}\right] \\
&= \mathrm{E}\left[XX^{\mathrm{T}} - X\,\mathrm{E}(X)^{\mathrm{T}} - \mathrm{E}(X)\,X^{\mathrm{T}} + \mathrm{E}(X)\mathrm{E}(X)^{\mathrm{T}}\right] \\
&= \mathrm{E}(XX^{\mathrm{T}}) - \mathrm{E}(X)\mathrm{E}(X)^{\mathrm{T}} - \mathrm{E}(X)\mathrm{E}(X)^{\mathrm{T}} + \mathrm{E}(X)\mathrm{E}(X)^{\mathrm{T}} \\
&= \mathrm{E}(XX^{\mathrm{T}}) - \mathrm{E}(X)\mathrm{E}(X)^{\mathrm{T}} \ .
\end{aligned}
\tag{4}
$$

1.7.8 Covariance matrix and correlation matrix

Theorem: Let X be a random vector ($\rightarrow$ Definition I/1.1.4). Then, the covariance matrix ($\rightarrow$ Definition I/1.7.6) of X can be expressed in terms of its correlation matrix ($\rightarrow$ Definition I/1.8.2) as follows

$$
\Sigma_{XX} = \mathrm{D}_X \cdot \mathrm{C}_{XX} \cdot \mathrm{D}_X \ ,
\tag{1}
$$

where D_X is a diagonal matrix with the standard deviations ($\rightarrow$ Definition I/1.10.1) of $X_1, \ldots, X_n$ as entries on the diagonal:

$$
\mathrm{D}_X = \mathrm{diag}(\sigma_{X_1}, \ldots, \sigma_{X_n}) = \begin{bmatrix} \sigma_{X_1} & \ldots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \ldots & \sigma_{X_n} \end{bmatrix} \ .
\tag{2}
$$

Proof: Reiterating (1) and applying (2), we have:

$$
\Sigma_{XX} = \begin{bmatrix} \sigma_{X_1} & \ldots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \ldots & \sigma_{X_n} \end{bmatrix} \cdot \mathrm{C}_{XX} \cdot \begin{bmatrix} \sigma_{X_1} & \ldots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \ldots & \sigma_{X_n} \end{bmatrix} \ .
\tag{3}
$$

Together with the definition of the correlation matrix ($\rightarrow$ Definition I/1.8.2), this gives

$$\Sigma_{XX} = \begin{bmatrix} \sigma_{X_1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sigma_{X_n} \end{bmatrix} \cdot \begin{bmatrix} \frac{\mathrm{E}[(X_1-\mathrm{E}[X_1])(X_1-\mathrm{E}[X_1])]}{\sigma_{X_1}\,\sigma_{X_1}} & \cdots & \frac{\mathrm{E}[(X_1-\mathrm{E}[X_1])(X_n-\mathrm{E}[X_n])]}{\sigma_{X_1}\,\sigma_{X_n}} \\ \vdots & \ddots & \vdots \\ \frac{\mathrm{E}[(X_n-\mathrm{E}[X_n])(X_1-\mathrm{E}[X_1])]}{\sigma_{X_n}\,\sigma_{X_1}} & \cdots & \frac{\mathrm{E}[(X_n-\mathrm{E}[X_n])(X_n-\mathrm{E}[X_n])]}{\sigma_{X_n}\,\sigma_{X_n}} \end{bmatrix} \cdot \begin{bmatrix} \sigma_{X_1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sigma_{X_n} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{\sigma_{X_1}\cdot\mathrm{E}[(X_1-\mathrm{E}[X_1])(X_1-\mathrm{E}[X_1])]}{\sigma_{X_1}\,\sigma_{X_1}} & \cdots & \frac{\sigma_{X_1}\cdot\mathrm{E}[(X_1-\mathrm{E}[X_1])(X_n-\mathrm{E}[X_n])]}{\sigma_{X_1}\,\sigma_{X_n}} \\ \vdots & \ddots & \vdots \\ \frac{\sigma_{X_n}\cdot\mathrm{E}[(X_n-\mathrm{E}[X_n])(X_1-\mathrm{E}[X_1])]}{\sigma_{X_n}\,\sigma_{X_1}} & \cdots & \frac{\sigma_{X_n}\cdot\mathrm{E}[(X_n-\mathrm{E}[X_n])(X_n-\mathrm{E}[X_n])]}{\sigma_{X_n}\,\sigma_{X_n}} \end{bmatrix} \cdot \begin{bmatrix} \sigma_{X_1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sigma_{X_n} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{\sigma_{X_1}\cdot\mathrm{E}[(X_1-\mathrm{E}[X_1])(X_1-\mathrm{E}[X_1])]\cdot\sigma_{X_1}}{\sigma_{X_1}\,\sigma_{X_1}} & \cdots & \frac{\sigma_{X_1}\cdot\mathrm{E}[(X_1-\mathrm{E}[X_1])(X_n-\mathrm{E}[X_n])]\cdot\sigma_{X_n}}{\sigma_{X_1}\,\sigma_{X_n}} \\ \vdots & \ddots & \vdots \\ \frac{\sigma_{X_n}\cdot\mathrm{E}[(X_n-\mathrm{E}[X_n])(X_1-\mathrm{E}[X_1])]\cdot\sigma_{X_1}}{\sigma_{X_n}\,\sigma_{X_1}} & \cdots & \frac{\sigma_{X_n}\cdot\mathrm{E}[(X_n-\mathrm{E}[X_n])(X_n-\mathrm{E}[X_n])]\cdot\sigma_{X_n}}{\sigma_{X_n}\,\sigma_{X_n}} \end{bmatrix}$$

$$= \begin{bmatrix} \mathrm{E}\left[(X_1-\mathrm{E}[X_1])(X_1-\mathrm{E}[X_1])\right] & \cdots & \mathrm{E}\left[(X_1-\mathrm{E}[X_1])(X_n-\mathrm{E}[X_n])\right] \\ \vdots & \ddots & \vdots \\ \mathrm{E}\left[(X_n-\mathrm{E}[X_n])(X_1-\mathrm{E}[X_1])\right] & \cdots & \mathrm{E}\left[(X_n-\mathrm{E}[X_n])(X_n-\mathrm{E}[X_n])\right] \end{bmatrix} \tag{4}$$

which is nothing else than the definition of the covariance matrix ($\rightarrow$ Definition I/1.7.6).

1.7.9 Precision matrix

Definition: Let $X = [X_1, \ldots, X_n]^{\mathrm{T}}$ be a random vector ($\rightarrow$ Definition I/1.1.4). Then, the precision matrix of X is defined as the inverse of the covariance matrix ($\rightarrow$ Definition I/1.7.6) of X:

$$\Lambda_{XX} = \Sigma_{XX}^{-1} = \begin{bmatrix} \mathrm{Cov}(X_1, X_1) & \cdots & \mathrm{Cov}(X_1, X_n) \\ \vdots & \ddots & \vdots \\ \mathrm{Cov}(X_n, X_1) & \cdots & \mathrm{Cov}(X_n, X_n) \end{bmatrix}^{-1} . \tag{1}$$

Sources:
- Wikipedia (2020): "Precision (statistics)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-06-06; URL: https://en.wikipedia.org/wiki/Precision_(statistics).

Metadata: ID: D74 | shortcut: precmat | author: JoramSoch | date: 2020-06-06, 05:08.

1.7.10   Precision matrix and correlation matrix

Theorem: Let X be a random vector ($\rightarrow$ Definition I/1.1.4). Then, the precision matrix ($\rightarrow$ Definition I/1.7.9) of X can be expressed in terms of its correlation matrix ($\rightarrow$ Definition I/1.8.2) as follows

$$\Lambda_{XX} = \mathrm{D}_X^{-1} \cdot \mathrm{C}_{XX}^{-1} \cdot \mathrm{D}_X^{-1} \, , \tag{1}$$

where D_X^{-1} is a diagonal matrix with the inverse standard deviations ($\rightarrow$ Definition I/1.10.1) of $X_1, \ldots, X_n$ as entries on the diagonal:

$$\mathrm{D}_X^{-1} = \mathrm{diag}(1/\sigma_{X_1}, \ldots, 1/\sigma_{X_n}) = \begin{bmatrix} \frac{1}{\sigma_{X_1}} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \frac{1}{\sigma_{X_n}} \end{bmatrix} . \tag{2}$$

Proof: The precision matrix ($\rightarrow$ Definition I/1.7.9) is defined as the inverse of the covariance matrix ($\rightarrow$ Definition I/1.7.6)

$$\Lambda_{XX} = \Sigma_{XX}^{-1} \tag{3}$$

and the relation between covariance matrix and correlation matrix ($\rightarrow$ Proof I/1.7.8) is given by

$$\Sigma_{XX} = \mathrm{D}_X \cdot \mathrm{C}_{XX} \cdot \mathrm{D}_X \tag{4}$$

where

$$\mathrm{D}_X = \mathrm{diag}(\sigma_{X_1}, \ldots, \sigma_{X_n}) = \begin{bmatrix} \sigma_{X_1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sigma_{X_n} \end{bmatrix} . \tag{5}$$

Using the matrix product property

$$(A \cdot B \cdot C)^{-1} = C^{-1} \cdot B^{-1} \cdot A^{-1} \tag{6}$$

and the diagonal matrix property

$$\mathrm{diag}(a_1, \ldots, a_n)^{-1} = \begin{bmatrix} a_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & a_n \end{bmatrix}^{-1} = \begin{bmatrix} \frac{1}{a_1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \frac{1}{a_n} \end{bmatrix} = \mathrm{diag}(1/a_1, \ldots, 1/a_n) \, , \tag{7}$$

we obtain

$$
\begin{aligned}
\Lambda_{XX} &\overset{(3)}{=} \Sigma_{XX}^{-1} \\
&\overset{(4)}{=} (\mathrm{D}_X \cdot \mathrm{C}_{XX} \cdot \mathrm{D}_X)^{-1} \\
&\overset{(6)}{=} \mathrm{D}_X^{-1} \cdot \mathrm{C}_{XX}^{-1} \cdot \mathrm{D}_X^{-1} \\
&\overset{(7)}{=}
\begin{bmatrix}
\frac{1}{\sigma_{X_1}} & \cdots & 0 \\
\vdots & \ddots & \vdots \\
0 & \cdots & \frac{1}{\sigma_{X_n}}
\end{bmatrix}
\cdot \mathrm{C}_{XX}^{-1} \cdot
\begin{bmatrix}
\frac{1}{\sigma_{X_1}} & \cdots & 0 \\
\vdots & \ddots & \vdots \\
0 & \cdots & \frac{1}{\sigma_{X_n}}
\end{bmatrix}
\end{aligned}
\tag{8}
$$

which conforms to equation (1).

1.8 Correlation

1.8.1 Definition

Definition: The correlation of two random variables ($\rightarrow$ Definition I/1.1.3) X and Y, also called Pearson product-moment correlation coefficient (PPMCC), is defined as the ratio of the covariance ($\rightarrow$ Definition I/1.7.1) of X and Y relative to the product of their standard deviations ($\rightarrow$ Definition I/1.10.1):

$$
\mathrm{Corr}(X, Y) = \frac{\sigma_{XY}}{\sigma_X \sigma_Y} = \frac{\mathrm{Cov}(X, Y)}{\sqrt{\mathrm{Var}(X)}\sqrt{\mathrm{Var}(Y)}} = \frac{\mathrm{E}\left[(X - \mathrm{E}[X])(Y - \mathrm{E}[Y])\right]}{\sqrt{\mathrm{E}\left[(X - \mathrm{E}[X])^2\right]}\sqrt{\mathrm{E}\left[(Y - \mathrm{E}[Y])^2\right]}} \; . \tag{1}
$$

1.8.2 Correlation matrix

Definition: Let $X = [X_1, \ldots, X_n]^{\mathrm{T}}$ be a random vector ($\rightarrow$ Definition I/1.1.4). Then, the correlation matrix of X is defined as the $n \times n$ matrix in which the entry (i, j) is the correlation ($\rightarrow$ Definition I/1.8.1) of X_i and X_j:

$$
\mathrm{C}_{XX} = \begin{bmatrix} \mathrm{Corr}(X_1, X_1) & \dots & \mathrm{Corr}(X_1, X_n) \\ \vdots & \ddots & \vdots \\ \mathrm{Corr}(X_n, X_1) & \dots & \mathrm{Corr}(X_n, X_n) \end{bmatrix} = \begin{bmatrix} \frac{\mathrm{E}[(X_1 - \mathrm{E}[X_1])(X_1 - \mathrm{E}[X_1])]}{\sigma_{X_1}\,\sigma_{X_1}} & \dots & \frac{\mathrm{E}[(X_1 - \mathrm{E}[X_1])(X_n - \mathrm{E}[X_n])]}{\sigma_{X_1}\,\sigma_{X_n}} \\ \vdots & \ddots & \vdots \\ \frac{\mathrm{E}[(X_n - \mathrm{E}[X_n])(X_1 - \mathrm{E}[X_1])]}{\sigma_{X_n}\,\sigma_{X_1}} & \dots & \frac{\mathrm{E}[(X_n - \mathrm{E}[X_n])(X_n - \mathrm{E}[X_n])]}{\sigma_{X_n}\,\sigma_{X_n}} \end{bmatrix} . \tag{1}
$$

1.9 Measures of central tendency

1.9.1 Median

Definition: The median of a sample or random variable is the value separating the higher half from the lower half of its values.

1) Let $x = \{x_1, \dots, x_n\}$ be a sample ($\to$ Definition "samp") from a random variable ($\to$ Definition I/1.1.3) X. Then, the median of x is

$$
\mathrm{median}(x) = \begin{cases} x_{(n+1)/2} \,, & \text{if } n \text{ is odd} \\ \frac{1}{2}(x_{n/2} + x_{n/2+1}) \,, & \text{if } n \text{ is even} \,, \end{cases} \tag{1}
$$

i.e. the median is the "middle" number when all numbers are sorted from smallest to largest.

2) Let X be a continuous random variable ($\to$ Definition I/1.1.3) with cumulative distribution function ($\to$ Definition I/1.4.8) $F_X(x)$. Then, the median of X is

$$
\mathrm{median}(X) = x, \quad \text{s.t.} \quad F_X(x) = \frac{1}{2} \,, \tag{2}
$$

i.e. the median is the value at which the CDF is 1/2.

Sources:
- Wikipedia (2020): "Median"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-10-15; URL: https://en.wikipedia.org/wiki/Median.

Metadata: ID: D101 | shortcut: med | author: JoramSoch | date: 2020-10-15, 10:53.

1.9.2 Mode

Definition: The mode of a sample or random variable is the value which occurs most often or with largest probability among all its values.

1) Let $x = \{x_1, \ldots, x_n\}$ be a sample ($\rightarrow$ Definition "samp") from a random variable ($\rightarrow$ Definition I/1.1.3) X. Then, the mode of x is the value which occurs most often in the list $x_1, \ldots, x_n$.

2) Let X be a random variable ($\rightarrow$ Definition I/1.1.3) with probability mass function ($\rightarrow$ Definition I/1.4.1) or probability density function ($\rightarrow$ Definition I/1.4.4) $f_X(x)$. Then, the mode of X is the the value which maximizes the PMF or PDF:

$$\mathrm{mode}(X) = \arg \max_x f_X(x) \, . \tag{1}$$

Sources:
- Wikipedia (2020): "Mode (statistics)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-10-15; URL: https://en.wikipedia.org/wiki/Mode_(statistics).

Metadata: ID: D102 | shortcut: mode | author: JoramSoch | date: 2020-10-15, 11:10.

1.10 Measures of statistical dispersion

1.10.1 Standard deviation

Definition: The standard deviation σ of a random variable ($\rightarrow$ Definition I/1.1.3) X with expected value ($\rightarrow$ Definition I/1.5.1) μ is defined as the square root of the variance ($\rightarrow$ Definition I/1.6.1), i.e.

$$\sigma(X) = \sqrt{\mathrm{E}\left[(X - \mu)^2\right]} \, . \tag{1}$$

Sources:
- Wikipedia (2020): "Standard deviation"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-09-03; URL: https://en.wikipedia.org/wiki/Standard_deviation#Definition_of_population_values.

Metadata: ID: D94 | shortcut: std | author: JoramSoch | date: 2020-09-03, 05:43.

1.10.2 Full width at half maximum

Definition: Let X be a continuous random variable ($\rightarrow$ Definition I/1.1.3) with a unimodal probability density function ($\rightarrow$ Definition I/1.4.4) $f_X(x)$ and mode ($\rightarrow$ Definition I/1.9.2) x_M. Then, the full width at half maximum of X is defined as

$$\mathrm{FHWM}(X) = \Delta x = x_2 - x_1 \tag{1}$$

where x_1 and x_2 are specified, such that

$$f_X(x_1) = f_X(x_2) = \frac{1}{2} f_X(x_M) \quad \text{and} \quad x_1 < x_M < x_2 \, . \tag{2}$$

Sources:
- Wikipedia (2020): "Full width at half maximum"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-08-19; URL: https://en.wikipedia.org/wiki/Full_width_at_half_maximum.

1.11   Further summary statistics

1.11.1   Minimum

Definition: The minimum of a sample or random variable is its lowest observed or possible value.

1) Let $x = \{x_1, \ldots, x_n\}$ be a sample ($\to$ Definition "samp") from a random variable ($\to$ Definition I/1.1.3) X. Then, the minimum of x is

$$\min(x) = x_j, \quad \text{such that} \quad x_j \leq x_i \quad \text{for all} \quad i = 1, \ldots, n,\ i \neq j\ , \tag{1}$$

i.e. the minimum is the value which is smaller than or equal to all other observed values.

2) Let X be a random variable ($\to$ Definition I/1.1.3) with possible values $\mathcal{X}$. Then, the minimum of X is

$$\min(X) = \tilde{x}, \quad \text{such that} \quad \tilde{x} < x \quad \text{for all} \quad x \in \mathcal{X} \setminus \{\tilde{x}\}\ , \tag{2}$$

i.e. the minimum is the value which is smaller than all other possible values.

Sources:
- Wikipedia (2020): "Sample maximum and minimum"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-11-12; URL: https://en.wikipedia.org/wiki/Sample_maximum_and_minimum.

Metadata: ID: D107 | shortcut: min | author: JoramSoch | date: 2020-11-12, 05:25.

1.11.2   Maximum

Definition: The maximum of a sample or random variable is its highest observed or possible value.

1) Let $x = \{x_1, \ldots, x_n\}$ be a sample ($\to$ Definition "samp") from a random variable ($\to$ Definition I/1.1.3) X. Then, the maximum of x is

$$\max(x) = x_j, \quad \text{such that} \quad x_j \geq x_i \quad \text{for all} \quad i = 1, \ldots, n,\ i \neq j\ , \tag{1}$$

i.e. the maximum is the value which is larger than or equal to all other observed values.

2) Let X be a random variable ($\to$ Definition I/1.1.3) with possible values $\mathcal{X}$. Then, the maximum of X is

$$\max(X) = \tilde{x}, \quad \text{such that} \quad \tilde{x} > x \quad \text{for all} \quad x \in \mathcal{X} \setminus \{\tilde{x}\}\ , \tag{2}$$

i.e. the maximum is the value which is larger than all other possible values.

Sources:
- Wikipedia (2020): "Sample maximum and minimum"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-11-12; URL: https://en.wikipedia.org/wiki/Sample_maximum_and_minimum.

1.12 Further moments

1.12.1 Moment

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3), let c be a constant ($\rightarrow$ Definition I/1.1.6) and let n be a positive integer. Then, the n-th moment of X about c is defined as the expected value ($\rightarrow$ Definition I/1.5.1) of the n-th power of X minus c:

$$\mu_n(c) = \mathrm{E}[(X - c)^n] \, . \tag{1}$$

The "n-th moment of X" may also refer to:
- the n-th raw moment ($\rightarrow$ Definition I/1.12.3) $\mu'_n = \mu_n(0)$;
- the n-th central moment ($\rightarrow$ Definition I/1.12.6) $\mu_n = \mu_n(\mu)$;
- the n-th standardized moment ($\rightarrow$ Definition I/1.12.9) $\mu^*_n = \mu_n/\sigma^n$.

Sources:
- Wikipedia (2020): "Moment (mathematics)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-08-19; URL: https://en.wikipedia.org/wiki/Moment_(mathematics)#Significance_of_the_ moments.

1.12.2 Moment in terms of moment-generating function

Theorem: Let X be a scalar random variable ($\rightarrow$ Definition I/1.1.3) with the moment-generating function ($\rightarrow$ Definition I/1.4.19) $M_X(t)$. Then, the n-th raw moment ($\rightarrow$ Definition I/1.12.3) of X can be calculated from the moment-generating function via

$$\mathrm{E}(X^n) = M_X^{(n)}(0) \tag{1}$$

where n is a positive integer and $M_X^{(n)}(t)$ is the n-th derivative of $M_X(t)$.

Proof: Using the definition of the moment-generating function ($\rightarrow$ Definition I/1.4.19), we can write:

$$M_X^{(n)}(t) = \frac{\mathrm{d}^n}{\mathrm{d}t^n} \mathrm{E}(e^{tX}) \, . \tag{2}$$

Using the power series expansion of the exponential function

$$e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!} \, , \tag{3}$$

equation (2) becomes

$$M_X^{(n)}(t) = \frac{\mathrm{d}^n}{\mathrm{d}t^n} \mathrm{E} \left(\sum_{m=0}^{\infty} \frac{t^m X^m}{m!} \right) \, . \tag{4}$$

Because the expected value is a linear operator ($\rightarrow$ Proof I/1.5.5), we have:

$$M_X^{(n)}(t) = \frac{\mathrm{d}^n}{\mathrm{d}t^n} \sum_{m=0}^{\infty} \mathrm{E}\left(\frac{t^m X^m}{m!}\right)$$

$$= \sum_{m=0}^{\infty} \frac{\mathrm{d}^n}{\mathrm{d}t^n} \frac{t^m}{m!} \mathrm{E}(X^m) \ . \tag{5}$$

Using the n-th derivative of the m-th power

$$\frac{\mathrm{d}^n}{\mathrm{d}x^n} x^m = \begin{cases} m^{\underline{n}} \, x^{m-n} \ , & \text{if } n \leq m \\ \\ 0 \ , & \text{if } n > m \ . \end{cases} \tag{6}$$

with the falling factorial

$$m^{\underline{n}} = \prod_{i=0}^{n-1} (m-i) = \frac{m!}{(m-n)!} \ , \tag{7}$$

equation (5) becomes

$$
\begin{aligned}
M_X^{(n)}(t) &= \sum_{m=n}^{\infty} \frac{m^{\underline{n}} \, t^{m-n}}{m!} \mathrm{E}(X^m) \\
&\overset{(7)}{=} \sum_{m=n}^{\infty} \frac{m! \, t^{m-n}}{(m-n)! \, m!} \mathrm{E}(X^m) \\
&= \sum_{m=n}^{\infty} \frac{t^{m-n}}{(m-n)!} \mathrm{E}(X^m) \\
&= \frac{t^{n-n}}{(n-n)!} \mathrm{E}(X^n) + \sum_{m=n+1}^{\infty} \frac{t^{m-n}}{(m-n)!} \mathrm{E}(X^m) \\
&= \frac{t^0}{0!} \, \mathrm{E}(X^n) + \sum_{m=n+1}^{\infty} \frac{t^{m-n}}{(m-n)!} \mathrm{E}(X^m) \\
&= \mathrm{E}(X^n) + \sum_{m=n+1}^{\infty} \frac{t^{m-n}}{(m-n)!} \mathrm{E}(X^m) \ .
\end{aligned}
\tag{8}
$$

Setting $t = 0$ in (8) yields

$$
\begin{aligned}
M_X^{(n)}(0) &= \mathrm{E}(X^n) + \sum_{m=n+1}^{\infty} \frac{0^{m-n}}{(m-n)!} \mathrm{E}(X^m) \\
&= \mathrm{E}(X^n)
\end{aligned}
\tag{9}
$$

which conforms to equation (1).

1.12.3 Raw moment

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) and let n be a positive integer. Then, the n-th raw moment of X, also called (n-th) "crude moment", is defined as the n-th moment ($\rightarrow$ Definition I/1.12.1) of X about the value 0:

$$\mu'_n = \mu_n(0) = \mathrm{E}[(X - 0)^n] = \mathrm{E}[X^n] \,. \tag{1}$$

Sources:
- Wikipedia (2020): "Moment (mathematics)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-10-08; URL: https://en.wikipedia.org/wiki/Moment_(mathematics)#Significance_of_the_moments.

1.12.4 First raw moment is mean

Theorem: The first raw moment ($\rightarrow$ Definition I/1.12.3) equals the mean ($\rightarrow$ Definition I/1.5.1), i.e.

$$\mu'_1 = \mu \,. \tag{1}$$

Proof: The first raw moment ($\rightarrow$ Definition I/1.12.3) of a random variable ($\rightarrow$ Definition I/1.1.3) X is defined as

$$\mu'_1 = \mathrm{E}\left[(X - 0)^1\right] \tag{2}$$

which is equal to the expected value ($\rightarrow$ Definition I/1.5.1) of X:

$$\mu'_1 = \mathrm{E}\left[X\right] = \mu \,. \tag{3}$$

1.12.5 Second raw moment and variance

Theorem: The second raw moment ($\rightarrow$ Definition I/1.12.3) can be expressed as

$$\mu'_2 = \mathrm{Var}(X) + \mathrm{E}(X)^2 \tag{1}$$

where $\mathrm{Var}(X)$ is the variance ($\rightarrow$ Definition I/1.6.1) of X and $\mathrm{E}(X)$ is the expected value ($\rightarrow$ Definition I/1.5.1) of X.

Proof: The second raw moment ($\rightarrow$ Definition I/1.12.3) of a random variable ($\rightarrow$ Definition I/1.1.3) X is defined as

$$\mu_2' = \mathrm{E}\left[(X - 0)^2\right] . \tag{2}$$

Using the partition of variance into expected values ($\rightarrow$ Proof I/1.6.3)

$$\mathrm{Var}(X) = \mathrm{E}(X^2) - \mathrm{E}(X)^2 , \tag{3}$$

the second raw moment can be rearranged into:

$$\mu_2' \overset{(2)}{=} \mathrm{E}(X^2) \overset{(3)}{=} \mathrm{Var}(X) + \mathrm{E}(X)^2 . \tag{4}$$

1.12.6 Central moment

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) with expected value ($\rightarrow$ Definition I/1.5.1) μ and let n be a positive integer. Then, the n-th central moment of X is defined as the n-th moment ($\rightarrow$ Definition I/1.12.1) of X about the value μ:

$$\mu_n = \mathrm{E}[(X - \mu)^n] . \tag{1}$$

Sources:
- Wikipedia (2020): "Moment (mathematics)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-10-08; URL: https://en.wikipedia.org/wiki/Moment_(mathematics)#Significance_of_the_moments.

Metadata: ID: D98 | shortcut: mom-cent | author: JoramSoch | date: 2020-10-08, 03:37.

1.12.7 First central moment is zero

Theorem: The first central moment ($\rightarrow$ Definition I/1.12.6) is zero, i.e.

$$\mu_1 = 0 . \tag{1}$$

Proof: The first central moment ($\rightarrow$ Definition I/1.12.6) of a random variable ($\rightarrow$ Definition I/1.1.3) X with mean ($\rightarrow$ Definition I/1.5.1) μ is defined as

$$\mu_1 = \mathrm{E}\left[(X - \mu)^1\right] . \tag{2}$$

Due to the linearity of the expected value ($\rightarrow$ Proof I/1.5.5) and by plugging in $\mu = \mathrm{E}(X)$, we have

$$\begin{aligned}
\mu_1 &= \mathrm{E}\left[X - \mu\right] \\
&= \mathrm{E}(X) - \mu \\
&= \mathrm{E}(X) - \mathrm{E}(X) \\
&= 0 \; .
\end{aligned} \tag{3}$$

Sources:
- ProofWiki (2020): "First Central Moment is Zero"; in: *ProofWiki*, retrieved on 2020-09-09; URL: https://proofwiki.org/wiki/First_Central_Moment_is_Zero.

1.12.8 Second central moment is variance

Theorem: The second central moment ($\to$ Definition I/1.12.6) equals the variance ($\to$ Definition I/1.6.1), i.e.

$$\mu_2 = \mathrm{Var}(X) \; . \tag{1}$$

Proof: The second central moment ($\to$ Definition I/1.12.6) of a random variable ($\to$ Definition I/1.1.3) X with mean ($\to$ Definition I/1.5.1) μ is defined as

$$\mu_2 = \mathrm{E}\left[(X - \mu)^2\right] \tag{2}$$

which is equivalent to the definition of the variance ($\to$ Definition I/1.6.1):

$$\mu_2 = \mathrm{E}\left[(X - \mathrm{E}(X))^2\right] = \mathrm{Var}(X) \; . \tag{3}$$

Sources:
- Wikipedia (2020): "Moment (mathematics)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-10-08; URL: https://en.wikipedia.org/wiki/Moment_(mathematics)#Significance_of_the_moments.

1.12.9 Standardized moment

Definition: Let X be a random variable ($\to$ Definition I/1.1.3) with expected value ($\to$ Definition I/1.5.1) μ and standard deviation ($\to$ Definition I/1.10.1) σ and let n be a positive integer. Then, the n-th standardized moment of X is defined as the n-th moment ($\to$ Definition I/1.12.1) of X about the value μ, divided by the n-th power of σ:

$$\mu_n^* = \frac{\mu_n}{\sigma^n} = \frac{\mathrm{E}[(X - \mu)^n]}{\sigma^n} \; . \tag{1}$$

Sources:

- Wikipedia (2020): "Moment (mathematics)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-10-08; URL: https://en.wikipedia.org/wiki/Moment_(mathematics)#Standardized_moments.

Metadata: ID: D99 | shortcut: mom-stand | author: JoramSoch | date: 2020-10-08, 03:47.

2 Information theory

2.1 Shannon entropy

2.1.1 Definition

Definition: Let X be a discrete random variable ($\to$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and the (observed or assumed) probability mass function ($\to$ Definition I/1.4.1) $p(x) = f_X(x)$. Then, the entropy (also referred to as "Shannon entropy") of X is defined as

$$H(X) = -\sum_{x \in \mathcal{X}} p(x) \cdot \log_b p(x) \tag{1}$$

where b is the base of the logarithm specifying in which unit the entropy is determined.

Sources:
- Shannon CE (1948): "A Mathematical Theory of Communication"; in: *Bell System Technical Journal*, vol. 27, iss. 3, pp. 379-423; URL: https://ieeexplore.ieee.org/document/6773024; DOI: 10.1002/j.1538-7305.1948.tb01338.x.

Metadata: ID: D15 | shortcut: ent | author: JoramSoch | date: 2020-02-19, 17:36.

2.1.2 Non-negativity

Theorem: The entropy of a discrete random variable ($\to$ Definition I/1.1.3) is a non-negative number:

$$H(X) \geq 0 \ . \tag{1}$$

Proof: The entropy of a discrete random variable ($\to$ Definition I/2.1.1) is defined as

$$H(X) = -\sum_{x \in \mathcal{X}} p(x) \cdot \log_b p(x) \tag{2}$$

The minus sign can be moved into the sum:

$$H(X) = \sum_{x \in \mathcal{X}} [p(x) \cdot (-\log_b p(x))] \tag{3}$$

Because the co-domain of probability mass functions ($\to$ Definition I/1.4.1) is $[0, 1]$, we can deduce:

$$
\begin{array}{ccccc}
0 & \leq & p(x) & \leq & 1 \\
-\infty & \leq & \log_b p(x) & \leq & 0 \\
0 & \leq & -\log_b p(x) & \leq & +\infty \\
0 & \leq & p(x) \cdot (-\log_b p(x)) & \leq & +\infty \ .
\end{array}
\tag{4}
$$

By convention, $0 \cdot \log_b(0)$ is taken to be 0 when calculating entropy, consistent with

$$\lim_{p \to 0} [p \log_b(p)] = 0 \ . \tag{5}$$

Taking this together, each addend in (3) is positive or zero and thus, the entire sum must also be non-negative.

Metadata: ID: P57 | shortcut: ent-nonneg | author: JoramSoch | date: 2020-02-19, 19:10.

2.1.3   Concavity

Theorem: The entropy ($\rightarrow$ Definition I/2.1.1) is concave in the probability mass function ($\rightarrow$ Definition I/1.4.1) p, i.e.

$$\mathrm{H}[\lambda p_1 + (1 - \lambda)p_2] \geq \lambda \mathrm{H}[p_1] + (1 - \lambda)\mathrm{H}[p_2] \tag{1}$$

where p_1 and p_2 are probability mass functions and $0 \leq \lambda \leq 1$.

Proof: Let X be a discrete random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let $u(x)$ be the probability mass function ($\rightarrow$ Definition I/1.4.1) of a discrete uniform distribution ($\rightarrow$ Definition II/1.1.1) on $X \in \mathcal{X}$. Then, the entropy ($\rightarrow$ Definition I/2.1.1) of an arbitrary probability mass function ($\rightarrow$ Definition I/1.4.1) $p(x)$ can be rewritten as

$$
\begin{aligned}
\mathrm{H}[p] &= -\sum_{x \in \mathcal{X}} p(x) \cdot \log p(x) \\
&= -\sum_{x \in \mathcal{X}} p(x) \cdot \log \frac{p(x)}{u(x)} u(x) \\
&= -\sum_{x \in \mathcal{X}} p(x) \cdot \log \frac{p(x)}{u(x)} - \sum_{x \in \mathcal{X}} p(x) \cdot \log u(x) \\
&= -\mathrm{KL}[p||u] - \log \frac{1}{|\mathcal{X}|} \sum_{x \in \mathcal{X}} p(x) \\
&= \log |\mathcal{X}| - \mathrm{KL}[p||u] \\
\log |\mathcal{X}| - \mathrm{H}[p] &= \mathrm{KL}[p||u]
\end{aligned}
\tag{2}
$$

where we have applied the definition of the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1), the probability mass function of the discrete uniform distribution ($\rightarrow$ Proof II/1.1.2) and the total sum over the probability mass function ($\rightarrow$ Definition I/1.4.1).

Note that the KL divergence is convex ($\rightarrow$ Proof I/2.5.5) in the pair of probability distributions ($\rightarrow$ Definition I/1.3.1) (p, q):

$$\mathrm{KL}[\lambda p_1 + (1 - \lambda)p_2 || \lambda q_1 + (1 - \lambda)q_2] \leq \lambda \mathrm{KL}[p_1||q_1] + (1 - \lambda)\mathrm{KL}[p_2||q_2] \tag{3}$$

A special case of this is given by

$$
\begin{aligned}
\mathrm{KL}[\lambda p_1 + (1 - \lambda)p_2 || \lambda u + (1 - \lambda)u] &\leq \lambda \mathrm{KL}[p_1||u] + (1 - \lambda)\mathrm{KL}[p_2||u] \\
\mathrm{KL}[\lambda p_1 + (1 - \lambda)p_2 || u] &\leq \lambda \mathrm{KL}[p_1||u] + (1 - \lambda)\mathrm{KL}[p_2||u]
\end{aligned}
\tag{4}
$$

and applying equation (2), we have

$$
\begin{aligned}
\log|\mathcal{X}| - \mathrm{H}[\lambda p_1 + (1-\lambda)p_2] &\le \lambda\left(\log|\mathcal{X}| - \mathrm{H}[p_1]\right) + (1-\lambda)\left(\log|\mathcal{X}| - \mathrm{H}[p_2]\right) \\
\log|\mathcal{X}| - \mathrm{H}[\lambda p_1 + (1-\lambda)p_2] &\le \log|\mathcal{X}| - \lambda\mathrm{H}[p_1] - (1-\lambda)\mathrm{H}[p_2] \\
-\mathrm{H}[\lambda p_1 + (1-\lambda)p_2] &\le -\lambda\mathrm{H}[p_1] - (1-\lambda)\mathrm{H}[p_2] \\
\mathrm{H}[\lambda p_1 + (1-\lambda)p_2] &\ge \lambda\mathrm{H}[p_1] + (1-\lambda)\mathrm{H}[p_2]
\end{aligned}
\tag{5}
$$

which is equivalent to (1).

2.1.4 Conditional entropy

Definition: Let X and Y be discrete random variables ($\to$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and $\mathcal{Y}$ and probability mass functions ($\to$ Definition I/1.4.1) $p(x)$ and $p(y)$. Then, the conditional entropy of Y given X or, entropy of Y conditioned on X, is defined as

$$
\mathrm{H}(Y|X) = \sum_{x\in\mathcal{X}} p(x) \cdot \mathrm{H}(Y|X=x)
\tag{1}
$$

where $\mathrm{H}(Y|X=x)$ is the (marginal) entropy ($\to$ Definition I/2.1.1) of Y, evaluated at x.

Sources:
- Cover TM, Thomas JA (1991): "Joint Entropy and Conditional Entropy"; in: *Elements of Information Theory*, ch. 2.2, p. 15; URL: https://www.wiley.com/en-us/Elements+of+Information+Theory%2C+2nd+Edition-p-9780471241959.

Metadata: ID: D17 | shortcut: ent-cond | author: JoramSoch | date: 2020-02-19, 18:08.

2.1.5 Joint entropy

Definition: Let X and Y be discrete random variables ($\to$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and $\mathcal{Y}$ and joint probability ($\to$ Definition I/1.2.2) mass function ($\to$ Definition I/1.4.1) $p(x,y)$. Then, the joint entropy of X and Y is defined as

$$
\mathrm{H}(X,Y) = -\sum_{x\in\mathcal{X}}\sum_{y\in\mathcal{Y}} p(x,y) \cdot \log_b p(x,y)
\tag{1}
$$

where b is the base of the logarithm specifying in which unit the entropy is determined.

Sources:
- Cover TM, Thomas JA (1991): "Joint Entropy and Conditional Entropy"; in: *Elements of Information Theory*, ch. 2.2, p. 16; URL: https://www.wiley.com/en-us/Elements+of+Information+Theory%2C+2nd+Edition-p-9780471241959.

Metadata: ID: D18 | shortcut: ent-joint | author: JoramSoch | date: 2020-02-19, 18:18.

2.1.6 Cross-entropy

Definition: Let X be a discrete random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let P and Q be two probability distributions ($\rightarrow$ Definition I/1.3.1) on X with the probability mass functions ($\rightarrow$ Definition I/1.4.1) $p(x)$ and $q(x)$. Then, the cross-entropy of Q relative to P is defined as

$$\mathrm{H}(P, Q) = -\sum_{x \in \mathcal{X}} p(x) \cdot \log_b q(x) \tag{1}$$

where b is the base of the logarithm specifying in which unit the cross-entropy is determined.

Sources:
- Wikipedia (2020): "Cross entropy"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-07-28; URL: https://en.wikipedia.org/wiki/Cross_entropy#Definition.

Metadata: ID: D85 | shortcut: ent-cross | author: JoramSoch | date: 2020-07-28, 02:51.

2.1.7 Convexity of cross-entropy

Theorem: The cross-entropy ($\rightarrow$ Definition I/2.1.6) is convex in the probability distribution ($\rightarrow$ Definition I/1.3.1) q, i.e.

$$\mathrm{H}[p, \lambda q_1 + (1 - \lambda) q_2] \leq \lambda \mathrm{H}[p, q_1] + (1 - \lambda) \mathrm{H}[p, q_2] \tag{1}$$

where p is a fixed and q_1 and q_2 are any two probability distributions and $0 \leq \lambda \leq 1$.

Proof: The relationship between Kullback-Leibler divergence, entropy and cross-entropy ($\rightarrow$ Proof I/2.5.8) is:

$$\mathrm{KL}[P||Q] = \mathrm{H}(P, Q) - \mathrm{H}(P) \, . \tag{2}$$

Note that the KL divergence is convex ($\rightarrow$ Proof I/2.5.5) in the pair of probability distributions ($\rightarrow$ Definition I/1.3.1) (p, q):

$$\mathrm{KL}[\lambda p_1 + (1 - \lambda) p_2 || \lambda q_1 + (1 - \lambda) q_2] \leq \lambda \mathrm{KL}[p_1 || q_1] + (1 - \lambda) \mathrm{KL}[p_2 || q_2] \tag{3}$$

A special case of this is given by

$$\mathrm{KL}[\lambda p + (1 - \lambda) p || \lambda q_1 + (1 - \lambda) q_2] \leq \lambda \mathrm{KL}[p || q_1] + (1 - \lambda) \mathrm{KL}[p || q_2]$$
$$\mathrm{KL}[p || \lambda q_1 + (1 - \lambda) q_2] \leq \lambda \mathrm{KL}[p || q_1] + (1 - \lambda) \mathrm{KL}[p || q_2] \tag{4}$$

and applying equation (2), we have

$$
\begin{aligned}
\mathrm{H}[p, \lambda q_1 + (1-\lambda)q_2] - \mathrm{H}[p] &\leq \lambda\left(\mathrm{H}[p, q_1] - \mathrm{H}[p]\right) + (1-\lambda)\left(\mathrm{H}[p, q_2] - \mathrm{H}[p]\right) \\
\mathrm{H}[p, \lambda q_1 + (1-\lambda)q_2] - \mathrm{H}[p] &\leq \lambda\mathrm{H}[p, q_1] + (1-\lambda)\mathrm{H}[p, q_2] - \mathrm{H}[p] \\
\mathrm{H}[p, \lambda q_1 + (1-\lambda)q_2] &\leq \lambda\mathrm{H}[p, q_1] + (1-\lambda)\mathrm{H}[p, q_2]
\end{aligned}
\tag{5}
$$

which is equivalent to (1).

Sources:

- gunes (2019): "Convexity of cross entropy"; in: *StackExchange CrossValidated*, retrieved on 2020-11-08; URL: https://stats.stackexchange.com/questions/394463/convexity-of-cross-entropy.

Metadata: ID: P150 | shortcut: entcross-conv | author: JoramSoch | date: 2020-08-11, 09:16.

2.1.8 Gibbs' inequality

Theorem: Let X be a discrete random variable ($\rightarrow$ Definition I/1.1.3) and consider two probability distributions ($\rightarrow$ Definition I/1.3.1) with probability mass functions ($\rightarrow$ Definition I/1.4.1) $p(x)$ and $q(x)$. Then, Gibbs' inequality states that the entropy ($\rightarrow$ Definition I/2.1.1) of X according to P is smaller than or equal to the cross-entropy ($\rightarrow$ Definition I/2.1.6) of P and Q:

$$
-\sum_{x \in \mathcal{X}} p(x) \log_b p(x) \leq -\sum_{x \in \mathcal{X}} p(x) \log_b q(x) .
\tag{1}
$$

Proof: Without loss of generality, we will use the natural logarithm, because a change in the base of the logarithm only implies multiplication by a constant:

$$
\log_b a = \frac{\ln a}{\ln b} .
\tag{2}
$$

Let I be the of all x for which $p(x)$ is non-zero. Then, proving (1) requires to show that

$$
\sum_{x \in I} p(x) \ln \frac{p(x)}{q(x)} \geq 0 .
\tag{3}
$$

Because $\ln x \leq x - 1$, i.e. $-\ln x \geq 1 - x$, for all $x > 0$, with equality only if $x = 1$, we can say about the left-hand side that

$$
\begin{aligned}
\sum_{x \in I} p(x) \ln \frac{p(x)}{q(x)} &\geq \sum_{x \in I} p(x)\left(1 - \frac{p(x)}{q(x)}\right) \\
&= \sum_{x \in I} p(x) - \sum_{x \in I} q(x) .
\end{aligned}
\tag{4}
$$

Finally, since $p(x)$ and $q(x)$ are probability mass functions ($\rightarrow$ Definition I/1.4.1), we have

$$0 \leq p(x) \leq 1, \quad \sum_{x \in I} p(x) = 1 \quad \text{and}$$
$$0 \leq q(x) \leq 1, \quad \sum_{x \in I} q(x) \leq 1 \ , \tag{5}$$

such that it follows from (4) that

$$\sum_{x \in I} p(x) \ln \frac{p(x)}{q(x)} \geq \sum_{x \in I} p(x) - \sum_{x \in I} q(x)$$
$$= 1 - \sum_{x \in I} q(x) \geq 0 \ . \tag{6}$$

2.1.9 Log sum inequality

Theorem: Let $a_1, \ldots, a_n$ and $b_1, \ldots, b_n$ be non-negative real numbers and define $a = \sum_{i=1}^{n} a_i$ and $b = \sum_{i=1}^{n} b_i$. Then, the log sum inequality states that

$$\sum_{i=1}^{n} a_i \log_c \frac{a_i}{b_i} \geq a \log_c \frac{a}{b} \ . \tag{1}$$

Proof: Without loss of generality, we will use the natural logarithm, because a change in the base of the logarithm only implies multiplication by a constant:

$$\log_c a = \frac{\ln a}{\ln c} \ . \tag{2}$$

Let $f(x) = x \ln x$. Then, the left-hand side of (1) can be rewritten as

$$\sum_{i=1}^{n} a_i \ln \frac{a_i}{b_i} = \sum_{i=1}^{n} b_i \, f\left(\frac{a_i}{b_i}\right)$$
$$= b \sum_{i=1}^{n} \frac{b_i}{b} \, f\left(\frac{a_i}{b_i}\right) \ . \tag{3}$$

Because $f(x)$ is a convex function and

$$\frac{b_i}{b} \geq 0$$
$$\sum_{i=1}^{n} \frac{b_i}{b} = 1 \ , \tag{4}$$

applying Jensen's inequality yields

$$
\begin{aligned}
b \sum_{i=1}^{n} \frac{b_i}{b} \, f\left(\frac{a_i}{b_i}\right) &\geq b \, f\left(\sum_{i=1}^{n} \frac{b_i}{b} \frac{a_i}{b_i}\right) \\
&= b \, f\left(\frac{1}{b} \sum_{i=1}^{n} a_i\right) \\
&= b \, f\left(\frac{a}{b}\right) \\
&= a \, \ln\frac{a}{b} \; .
\end{aligned}
\tag{5}
$$

Finally, combining (3) and (5), this demonstrates (1).

2.2 Differential entropy

2.2.1 Definition

Definition: Let X be a continuous random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and the (estimated or assumed) probability density function ($\rightarrow$ Definition I/1.4.4) $p(x) = f_X(x)$. Then, the differential entropy (also referred to as "continuous entropy") of X is defined as

$$
\mathrm{h}(X) = -\int_{\mathcal{X}} p(x) \log_b p(x) \, \mathrm{d}x
\tag{1}
$$

where b is the base of the logarithm specifying in which unit the entropy is determined.

Sources:
- Cover TM, Thomas JA (1991): "Differential Entropy"; in: *Elements of Information Theory*, ch. 8.1, p. 243; URL: https://www.wiley.com/en-us/Elements+of+Information+Theory%2C+2nd+Edition-p-9780471241959.

Metadata: ID: D16 | shortcut: dent | author: JoramSoch | date: 2020-02-19, 17:53.

2.2.2 Negativity

Theorem: Unlike its discrete analogue ($\rightarrow$ Proof I/2.1.2), the differential entropy ($\rightarrow$ Definition I/2.2.1) can become negative.

Proof: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a continuous uniform distribution ($\rightarrow$ Definition II/3.1.1) with minimum 0 and maximum 1/2:

$$X \sim \mathcal{U}(0, 1/2) \, . \tag{1}$$

Then, its probability density function ($\rightarrow$ Proof II/3.1.2) is:

$$f_X(x) = 2 \quad \text{for} \quad 0 \le x \le \frac{1}{2} \, . \tag{2}$$

Thus, the differential entropy ($\rightarrow$ Definition I/2.2.1) follows as

$$
\begin{aligned}
\mathrm{h}(X) &= -\int_{\mathcal{X}} f_X(x) \log_b f_X(x) \, \mathrm{d}x \\
&= -\int_0^{\frac{1}{2}} 2 \log_b(2) \, \mathrm{d}x \\
&= -\log_b(2) \int_0^{\frac{1}{2}} 2 \, \mathrm{d}x \\
&= -\log_b(2) \, [2x]_0^{\frac{1}{2}} \\
&= -\log_b(2)
\end{aligned}
\tag{3}
$$

which is negative for any base $b > 1$.

- Wikipedia (2020): "Differential entropy"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-02; URL: https://en.wikipedia.org/wiki/Differential_entropy#Definition.

Metadata: ID: P68 | shortcut: dent-neg | author: JoramSoch | date: 2020-03-02, 20:32.

2.2.3 Invariance under addition

Theorem: Let X be a continuous ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3). Then, the differential entropy ($\rightarrow$ Definition I/2.2.1) of X remains constant under addition of a constant:

$$\mathrm{h}(X + c) = \mathrm{h}(X) \, . \tag{1}$$

Proof: By definition, the differential entropy ($\rightarrow$ Definition I/2.2.1) of X is

$$\mathrm{h}(X) = -\int_{\mathcal{X}} p(x) \log p(x) \, \mathrm{d}x \tag{2}$$

where $p(x) = f_X(x)$ is the probability density function ($\rightarrow$ Definition I/1.4.4) of X.
Define the mappings between X and $Y = X + c$ as

$$Y = g(X) = X + c \quad \Leftrightarrow \quad X = g^{-1}(Y) = Y - c \, . \tag{3}$$

Note that $g(X)$ is a strictly increasing function, such that the probability density function ($\rightarrow$ Proof I/1.4.5) of Y is

$$f_Y(y) = f_X(g^{-1}(y)) \, \frac{\mathrm{d}g^{-1}(y)}{\mathrm{d}y} \overset{(3)}{=} f_X(y - c) \, . \tag{4}$$

Writing down the differential entropy for Y, we have:

$$
\begin{aligned}
\mathrm{h}(Y) &= -\int_{\mathcal{Y}} f_Y(y) \log f_Y(y) \, \mathrm{d}y \\
&\overset{(4)}{=} -\int_{\mathcal{Y}} f_X(y - c) \log f_X(y - c) \, \mathrm{d}y
\end{aligned}
\tag{5}
$$

Substituting $x = y - c$, such that $y = x + c$, this yields:

$$
\begin{aligned}
\mathrm{h}(Y) &= -\int_{\{y - c \,|\, y \in \mathcal{Y}\}} f_X(x + c - c) \log f_X(x + c - c) \, \mathrm{d}(x + c) \\
&= -\int_{\mathcal{X}} f_X(x) \log f_X(x) \, \mathrm{d}x \\
&\overset{(2)}{=} \mathrm{h}(X) \,.
\end{aligned}
\tag{6}
$$

Sources:
- Wikipedia (2020): "Differential entropy"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-12; URL: https://en.wikipedia.org/wiki/Differential_entropy#Properties_of_differential_entropy.

2.2.4 Addition upon multiplication

Theorem: Let X be a continuous ($\rightarrow$ Definition I/1.1.7) random variable ($\rightarrow$ Definition I/1.1.3). Then, the differential entropy ($\rightarrow$ Definition I/2.2.1) of X increases additively upon multiplication with a constant:

$$
\mathrm{h}(aX) = \mathrm{h}(X) + \log |a| \,.
\tag{1}
$$

Proof: By definition, the differential entropy ($\rightarrow$ Definition I/2.2.1) of X is

$$
\mathrm{h}(X) = -\int_{\mathcal{X}} p(x) \log p(x) \, \mathrm{d}x
\tag{2}
$$

where $p(x) = f_X(x)$ is the probability density function ($\rightarrow$ Definition I/1.4.4) of X.
Define the mappings between X and $Y = aX$ as

$$
Y = g(X) = aX \quad \Leftrightarrow \quad X = g^{-1}(Y) = \frac{Y}{a} \,.
\tag{3}
$$

If $a > 0$, then $g(X)$ is a strictly increasing function, such that the probability density function ($\rightarrow$ Proof I/1.4.5) of Y is

$$
f_Y(y) = f_X(g^{-1}(y)) \frac{\mathrm{d}g^{-1}(y)}{\mathrm{d}y} \overset{(3)}{=} \frac{1}{a} f_X\left(\frac{y}{a}\right) \,;
\tag{4}
$$

if $a < 0$, then $g(X)$ is a strictly decreasing function, such that the probability density function ($\rightarrow$ Proof I/1.4.6) of Y is

$$f_Y(y) = -f_X(g^{-1}(y)) \frac{\mathrm{d}g^{-1}(y)}{\mathrm{d}y} \overset{(3)}{=} -\frac{1}{a} f_X\left(\frac{y}{a}\right) \; ; \tag{5}$$

thus, we can write

$$f_Y(y) = \frac{1}{|a|} f_X\left(\frac{y}{a}\right) \; . \tag{6}$$

Writing down the differential entropy for Y, we have:

$$
\begin{aligned}
\mathrm{h}(Y) &= -\int_{\mathcal{Y}} f_Y(y) \log f_Y(y) \, \mathrm{d}y \\
&\overset{(6)}{=} -\int_{\mathcal{Y}} \frac{1}{|a|} f_X\left(\frac{y}{a}\right) \log\left[\frac{1}{|a|} f_X\left(\frac{y}{a}\right)\right] \, \mathrm{d}y
\end{aligned}
\tag{7}
$$

Substituting $x = y/a$, such that $y = ax$, this yields:

$$
\begin{aligned}
\mathrm{h}(Y) &= -\int_{\{y/a \,|\, y \in \mathcal{Y}\}} \frac{1}{|a|} f_X\left(\frac{ax}{a}\right) \log\left[\frac{1}{|a|} f_X\left(\frac{ax}{a}\right)\right] \, \mathrm{d}(ax) \\
&= -\int_{\mathcal{X}} f_X(x) \log\left[\frac{1}{|a|} f_X(x)\right] \, \mathrm{d}x \\
&= -\int_{\mathcal{X}} f_X(x) \left[\log f_X(x) - \log|a|\right] \, \mathrm{d}x \\
&= -\int_{\mathcal{X}} f_X(x) \log f_X(x) \, \mathrm{d}x + \log|a| \int_{\mathcal{X}} f_X(x) \, \mathrm{d}x \\
&\overset{(2)}{=} \mathrm{h}(X) + \log|a| \; .
\end{aligned}
\tag{8}
$$

2.2.5 Conditional differential entropy

Definition: Let X and Y be continuous random variables ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and $\mathcal{Y}$ and probability density functions ($\rightarrow$ Definition I/1.4.4) $p(x)$ and $p(y)$. Then, the conditional differential entropy of Y given X or, differential entropy of Y conditioned on X, is defined as

$$\mathrm{h}(Y|X) = \int_{x \in \mathcal{X}} p(x) \cdot \mathrm{h}(Y|X = x) \tag{1}$$

where $\mathrm{h}(Y|X = x)$ is the (marginal) differential entropy ($\rightarrow$ Definition I/2.2.1) of Y, evaluated at x.

Sources:
- original work

Metadata: ID: D34 | shortcut: dent-cond | author: JoramSoch | date: 2020-03-21, 12:27.

2.2.6   Joint differential entropy

Definition: Let X and Y be continuous random variables ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and $\mathcal{Y}$ and joint probability ($\rightarrow$ Definition I/1.2.2) density function ($\rightarrow$ Definition I/1.4.4) $p(x, y)$. Then, the joint differential entropy of X and Y is defined as

$$\mathrm{h}(X, Y) = -\int_{x \in \mathcal{X}} \int_{y \in \mathcal{Y}} p(x, y) \cdot \log_b p(x, y) \, \mathrm{d}y \, \mathrm{d}x \tag{1}$$

where b is the base of the logarithm specifying in which unit the differential entropy is determined.

Sources:
- original work

Metadata: ID: D35 | shortcut: dent-joint | author: JoramSoch | date: 2020-03-21, 12:37.

2.2.7   Differential cross-entropy

Definition: Let X be a continuous random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let P and Q be two probability distributions ($\rightarrow$ Definition I/1.3.1) on X with the probability density functions ($\rightarrow$ Definition I/1.4.4) $p(x)$ and $q(x)$. Then, the differential cross-entropy of Q relative to P is defined as

$$\mathrm{h}(P, Q) = -\int_{\mathcal{X}} p(x) \log_b q(x) \, \mathrm{d}x \tag{1}$$

where b is the base of the logarithm specifying in which unit the differential cross-entropy is determined.

2.3   Discrete mutual information

2.3.1   Definition

Definition:
1) The mutual information of two discrete random variables ($\rightarrow$ Definition I/1.1.3) X and Y is defined as

$$\mathrm{I}(X, Y) = -\sum_{x \in \mathcal{X}} \sum_{x \in \mathcal{Y}} p(x, y) \cdot \log \frac{p(x, y)}{p(x) \cdot p(y)} \tag{1}$$

where $p(x)$ and $p(y)$ are the probability mass functions ($\rightarrow$ Definition I/1.4.1) of X and Y and $p(x, y)$ is the joint probability ($\rightarrow$ Definition I/1.2.2) mass function of X and Y.

2) The mutual information of two continuous random variables ($\rightarrow$ Definition I/1.1.3) X and Y is defined as

$$\mathrm{I}(X, Y) = - \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \cdot \log \frac{p(x, y)}{p(x) \cdot p(y)} \, \mathrm{d}y \, \mathrm{d}x \tag{2}$$

where $p(x)$ and $p(y)$ are the probability density functions ($\rightarrow$ Definition I/1.4.1) of X and Y and $p(x, y)$ is the joint probability ($\rightarrow$ Definition I/1.2.2) density function of X and Y.

2.3.2 Relation to marginal and conditional entropy

Theorem: Let X and Y be discrete random variables ($\rightarrow$ Definition I/1.1.3) with the joint probability ($\rightarrow$ Definition I/1.2.2) $p(x, y)$ for $x \in \mathcal{X}$ and $y \in \mathcal{Y}$. Then, the mutual information ($\rightarrow$ Definition I/2.4.1) of X and Y can be expressed as

$$
\begin{aligned}
\mathrm{I}(X, Y) &= \mathrm{H}(X) - \mathrm{H}(X|Y) \\
&= \mathrm{H}(Y) - \mathrm{H}(Y|X)
\end{aligned}
\tag{1}
$$

where $\mathrm{H}(X)$ and $\mathrm{H}(Y)$ are the marginal entropies ($\rightarrow$ Definition I/2.1.1) of X and Y and $\mathrm{H}(X|Y)$ and $\mathrm{H}(Y|X)$ are the conditional entropies ($\rightarrow$ Definition I/2.1.4).

Proof: The mutual information ($\rightarrow$ Definition I/2.4.1) of X and Y is defined as

$$\mathrm{I}(X, Y) = \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} p(x, y) \log \frac{p(x, y)}{p(x) \, p(y)} \, . \tag{2}$$

Separating the logarithm, we have:

$$\mathrm{I}(X, Y) = \sum_{x} \sum_{y} p(x, y) \log \frac{p(x, y)}{p(y)} - \sum_{x} \sum_{y} p(x, y) \log p(x) \, . \tag{3}$$

Applying the law of conditional probability ($\rightarrow$ Definition I/1.2.4), i.e. $p(x, y) = p(x|y) \, p(y)$, we get:

$$\mathrm{I}(X, Y) = \sum_{x} \sum_{y} p(x|y) \, p(y) \log p(x|y) - \sum_{x} \sum_{y} p(x, y) \log p(x) \, . \tag{4}$$

Regrouping the variables, we have:

$$\mathrm{I}(X, Y) = \sum_{y} p(y) \sum_{x} p(x|y) \log p(x|y) - \sum_{x} \left(\sum_{y} p(x, y) \right) \log p(x) \, . \tag{5}$$

Applying the law of marginal probability ($\rightarrow$ Definition I/1.2.3), i.e. $p(x) = \sum_{y} p(x, y)$, we get:

$$\mathrm{I}(X,Y) = \sum_y p(y) \sum_x p(x|y) \log p(x|y) - \sum_x p(x) \log p(x) \ . \tag{6}$$

Now considering the definitions of marginal ($\rightarrow$ Definition I/2.1.1) and conditional ($\rightarrow$ Definition I/2.1.4) entropy

$$\begin{aligned} \mathrm{H}(X) &= -\sum_{x \in \mathcal{X}} p(x) \log p(x) \\ \mathrm{H}(X|Y) &= \sum_{y \in \mathcal{Y}} p(y) \, \mathrm{H}(X|Y = y) \ , \end{aligned} \tag{7}$$

we can finally show:

$$\begin{aligned} \mathrm{I}(X,Y) &= -\mathrm{H}(X|Y) + \mathrm{H}(X) \\ &= \mathrm{H}(X) - \mathrm{H}(X|Y) \ . \end{aligned} \tag{8}$$

The conditioning of X on Y in this proof is without loss of generality. Thus, the proof for the expression using the reverse conditional entropy of Y given X is obtained by simply switching x and y in the derivation.

Sources:
- Wikipedia (2020): "Mutual information"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-01-13; URL: https://en.wikipedia.org/wiki/Mutual_information#Relation_to_conditional_and_joint_entropy.

2.3.3 Relation to marginal and joint entropy

Theorem: Let X and Y be discrete random variables ($\rightarrow$ Definition I/1.1.3) with the joint probability ($\rightarrow$ Definition I/1.2.2) $p(x,y)$ for $x \in \mathcal{X}$ and $y \in \mathcal{Y}$. Then, the mutual information ($\rightarrow$ Definition I/2.4.1) of X and Y can be expressed as

$$\mathrm{I}(X,Y) = \mathrm{H}(X) + \mathrm{H}(Y) - \mathrm{H}(X,Y) \tag{1}$$

where $\mathrm{H}(X)$ and $\mathrm{H}(Y)$ are the marginal entropies ($\rightarrow$ Definition I/2.1.1) of X and Y and $\mathrm{H}(X,Y)$ is the joint entropy ($\rightarrow$ Definition I/2.1.5).

Proof: The mutual information ($\rightarrow$ Definition I/2.4.1) of X and Y is defined as

$$\mathrm{I}(X,Y) = \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} p(x,y) \log \frac{p(x,y)}{p(x)\,p(y)} \ . \tag{2}$$

Separating the logarithm, we have:

$$\mathrm{I}(X,Y) = \sum_x \sum_y p(x,y) \log p(x,y) - \sum_x \sum_y p(x,y) \log p(x) - \sum_x \sum_y p(x,y) \log p(y) \ . \tag{3}$$

Regrouping the variables, this reads:

$$\mathrm{I}(X,Y) = \sum_x \sum_y p(x,y) \log p(x,y) - \sum_x \left(\sum_y p(x,y) \right) \log p(x) - \sum_y \left(\sum_x p(x,y) \right) \log p(y) \ . \quad (4)$$

Applying the law of marginal probability ($\to$ Definition I/1.2.3), i.e. $p(x) = \sum_y p(x,y)$, we get:

$$\mathrm{I}(X,Y) = \sum_x \sum_y p(x,y) \log p(x,y) - \sum_x p(x) \log p(x) - \sum_y p(y) \log p(y) \ . \quad (5)$$

Now considering the definitions of marginal ($\to$ Definition I/2.1.1) and joint ($\to$ Definition I/2.1.5) entropy

$$\begin{aligned} \mathrm{H}(X) &= -\sum_{x \in \mathcal{X}} p(x) \log p(x) \\ \mathrm{H}(X,Y) &= -\sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} p(x,y) \log p(x,y) \ , \end{aligned} \quad (6)$$

we can finally show:

$$\begin{aligned} \mathrm{I}(X,Y) &= -\mathrm{H}(X,Y) + \mathrm{H}(X) + \mathrm{H}(Y) \\ &= \mathrm{H}(X) + \mathrm{H}(Y) - \mathrm{H}(X,Y) \ . \end{aligned} \quad (7)$$

Sources:
- Wikipedia (2020): "Mutual information"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-01-13; URL: https://en.wikipedia.org/wiki/Mutual_information#Relation_to_conditional_and_joint_entropy.

Metadata: ID: P20 | shortcut: dmi-mje | author: JoramSoch | date: 2020-01-13, 21:53.

2.3.4 Relation to joint and conditional entropy

Theorem: Let X and Y be discrete random variables ($\to$ Definition I/1.1.3) with the joint probability ($\to$ Definition I/1.2.2) $p(x,y)$ for $x \in \mathcal{X}$ and $y \in \mathcal{Y}$. Then, the mutual information ($\to$ Definition I/2.4.1) of X and Y can be expressed as

$$\mathrm{I}(X,Y) = \mathrm{H}(X,Y) - \mathrm{H}(X|Y) - \mathrm{H}(Y|X) \quad (1)$$

where $\mathrm{H}(X,Y)$ is the joint entropy ($\to$ Definition I/2.1.5) of X and Y and $\mathrm{H}(X|Y)$ and $\mathrm{H}(Y|X)$ are the conditional entropies ($\to$ Definition I/2.1.4).

Proof: The existence of the joint probability mass function ($\to$ Definition I/1.4.1) ensures that the mutual information ($\to$ Definition I/2.4.1) is defined:

$$\mathrm{I}(X,Y) = \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} p(x,y) \log \frac{p(x,y)}{p(x)\,p(y)} \ . \quad (2)$$

The relation of mutual information to conditional entropy ($\to$ Proof I/2.3.2) is:

$$\mathrm{I}(X,Y) = \mathrm{H}(X) - \mathrm{H}(X|Y) \tag{3}$$

$$\mathrm{I}(X,Y) = \mathrm{H}(Y) - \mathrm{H}(Y|X) \tag{4}$$

The relation of mutual information to joint entropy ($\to$ Proof I/2.3.3) is:

$$\mathrm{I}(X,Y) = \mathrm{H}(X) + \mathrm{H}(Y) - \mathrm{H}(X,Y) \ . \tag{5}$$

It is true that

$$\mathrm{I}(X,Y) = \mathrm{I}(X,Y) + \mathrm{I}(X,Y) - \mathrm{I}(X,Y) \ . \tag{6}$$

Plugging in (3), (4) and (5) on the right-hand side, we have

$$\begin{aligned} \mathrm{I}(X,Y) &= \mathrm{H}(X) - \mathrm{H}(X|Y) + \mathrm{H}(Y) - \mathrm{H}(Y|X) - \mathrm{H}(X) - \mathrm{H}(Y) + \mathrm{H}(X,Y) \\ &= \mathrm{H}(X,Y) - \mathrm{H}(X|Y) - \mathrm{H}(Y|X) \end{aligned} \tag{7}$$

which proves the identity given above.

2.4.2   Relation to marginal and conditional differential entropy

Theorem: Let X and Y be continuous random variables ($\rightarrow$ Definition I/1.1.3) with the joint probability ($\rightarrow$ Definition I/1.2.2) $p(x, y)$ for $x \in \mathcal{X}$ and $y \in \mathcal{Y}$. Then, the mutual information ($\rightarrow$ Definition I/2.4.1) of X and Y can be expressed as

$$
\begin{aligned}
\mathrm{I}(X, Y) &= \mathrm{h}(X) - \mathrm{h}(X|Y) \\
&= \mathrm{h}(Y) - \mathrm{h}(Y|X)
\end{aligned}
\tag{1}
$$

where $\mathrm{h}(X)$ and $\mathrm{h}(Y)$ are the marginal differential entropies ($\rightarrow$ Definition I/2.2.1) of X and Y and $\mathrm{h}(X|Y)$ and $\mathrm{h}(Y|X)$ are the conditional differential entropies ($\rightarrow$ Definition I/2.2.5).

Proof: The mutual information ($\rightarrow$ Definition I/2.4.1) of X and Y is defined as

$$
\mathrm{I}(X, Y) = \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \log \frac{p(x, y)}{p(x)\, p(y)} \, \mathrm{d}y \, \mathrm{d}x \; .
\tag{2}
$$

Separating the logarithm, we have:

$$
\mathrm{I}(X, Y) = \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \log \frac{p(x, y)}{p(y)} \, \mathrm{d}y \, \mathrm{d}x - \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \log p(x) \, \mathrm{d}x \, \mathrm{d}y \; .
\tag{3}
$$

Applying the law of conditional probability ($\rightarrow$ Definition I/1.2.4), i.e. $p(x, y) = p(x|y)\, p(y)$, we get:

$$
\mathrm{I}(X, Y) = \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x|y)\, p(y) \log p(x|y) \, \mathrm{d}y \, \mathrm{d}x - \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \log p(x) \, \mathrm{d}y \, \mathrm{d}x \; .
\tag{4}
$$

Regrouping the variables, we have:

$$
\mathrm{I}(X, Y) = \int_{\mathcal{Y}} p(y) \int_{\mathcal{X}} p(x|y) \log p(x|y) \, \mathrm{d}x \, \mathrm{d}y - \int_{\mathcal{X}} \left(\int_{\mathcal{Y}} p(x, y) \, \mathrm{d}y \right) \log p(x) \, \mathrm{d}x \; .
\tag{5}
$$

Applying the law of marginal probability ($\rightarrow$ Definition I/1.2.3), i.e. $p(x) = \int_{\mathcal{Y}} p(x, y) \, \mathrm{d}y$, we get:

$$
\mathrm{I}(X, Y) = \int_{\mathcal{Y}} p(y) \int_{\mathcal{X}} p(x|y) \log p(x|y) \, \mathrm{d}x \, \mathrm{d}y - \int_{\mathcal{X}} p(x) \log p(x) \, \mathrm{d}x \; .
\tag{6}
$$

Now considering the definitions of marginal ($\rightarrow$ Definition I/2.2.1) and conditional ($\rightarrow$ Definition I/2.2.5) differential entropy

$$
\begin{aligned}
\mathrm{h}(X) &= - \int_{\mathcal{X}} p(x) \log p(x) \, \mathrm{d}x \\
\mathrm{h}(X|Y) &= \int_{\mathcal{Y}} p(y)\, \mathrm{h}(X|Y = y) \, \mathrm{d}y \; ,
\end{aligned}
\tag{7}
$$

we can finally show:

$$I(X, Y) = -h(X|Y) + h(X) = h(X) - h(X|Y) . \tag{8}$$

The conditioning of X on Y in this proof is without loss of generality. Thus, the proof for the expression using the reverse conditional differential entropy of Y given X is obtained by simply switching x and y in the derivation.

2.4.3 Relation to marginal and joint differential entropy

Theorem: Let X and Y be continuous random variables ($\rightarrow$ Definition I/1.1.3) with the joint probability ($\rightarrow$ Definition I/1.2.2) $p(x, y)$ for $x \in \mathcal{X}$ and $y \in \mathcal{Y}$. Then, the mutual information ($\rightarrow$ Definition I/2.4.1) of X and Y can be expressed as

$$I(X, Y) = h(X) + h(Y) - h(X, Y) \tag{1}$$

where $h(X)$ and $h(Y)$ are the marginal differential entropies ($\rightarrow$ Definition I/2.2.1) of X and Y and $h(X, Y)$ is the joint differential entropy ($\rightarrow$ Definition I/2.2.6).

Proof: The mutual information ($\rightarrow$ Definition I/2.4.1) of X and Y is defined as

$$I(X, Y) = \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \log \frac{p(x, y)}{p(x)\, p(y)} \, \mathrm{d}y \, \mathrm{d}x . \tag{2}$$

Separating the logarithm, we have:

$$I(X, Y) = \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \log p(x, y) \, \mathrm{d}y \, \mathrm{d}x - \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \log p(x) \, \mathrm{d}y \, \mathrm{d}x - \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \log p(y) \, \mathrm{d}y \, \mathrm{d}x . \tag{3}$$

Regrouping the variables, this reads:

$$I(X, Y) = \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \log p(x, y) \, \mathrm{d}y \, \mathrm{d}x - \int_{\mathcal{X}} \left(\int_{\mathcal{Y}} p(x, y) \, \mathrm{d}y \right) \log p(x) \, \mathrm{d}x - \int_{\mathcal{Y}} \left(\int_{\mathcal{X}} p(x, y) \, \mathrm{d}x \right) \log p(y) \, \mathrm{d}y . \tag{4}$$

Applying the law of marginal probability ($\rightarrow$ Definition I/1.2.3), i.e. $p(x) = \int_{\mathcal{Y}} p(x, y)$, we get:

$$I(X, Y) = \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x, y) \log p(x, y) \, \mathrm{d}y \, \mathrm{d}x - \int_{\mathcal{X}} p(x) \log p(x) \, \mathrm{d}x - \int_{\mathcal{Y}} p(y) \log p(y) \, \mathrm{d}y . \tag{5}$$

Now considering the definitions of marginal ($\rightarrow$ Definition I/2.2.1) and joint ($\rightarrow$ Definition I/2.2.6) differential entropy

$$\mathrm{h}(X) = -\int_{\mathcal{X}} p(x) \log p(x)\, \mathrm{d}x$$

$$\mathrm{h}(X,Y) = -\int_{\mathcal{X}} \int_{\mathcal{Y}} p(x,y) \log p(x,y)\, \mathrm{d}y\, \mathrm{d}x\ ,$$

(6)

we can finally show:

$$\begin{aligned}
\mathrm{I}(X,Y) &= -\mathrm{h}(X,Y) + \mathrm{h}(X) + \mathrm{h}(Y) \\
&= \mathrm{h}(X) + \mathrm{h}(Y) - \mathrm{h}(X,Y)\ .
\end{aligned}$$

(7)

2.4.4 Relation to joint and conditional differential entropy

Theorem: Let X and Y be continuous random variables ($\rightarrow$ Definition I/1.1.3) with the joint probability ($\rightarrow$ Definition I/1.2.2) $p(x,y)$ for $x \in \mathcal{X}$ and $y \in \mathcal{Y}$. Then, the mutual information ($\rightarrow$ Definition I/2.4.1) of X and Y can be expressed as

$$\mathrm{I}(X,Y) = \mathrm{h}(X,Y) - \mathrm{h}(X|Y) - \mathrm{h}(Y|X)$$

(1)

where $\mathrm{h}(X,Y)$ is the joint differential entropy ($\rightarrow$ Definition I/2.2.6) of X and Y and $\mathrm{h}(X|Y)$ and $\mathrm{h}(Y|X)$ are the conditional differential entropies ($\rightarrow$ Definition I/2.2.5).

Proof: The existence of the joint probability density function ($\rightarrow$ Definition I/1.4.4) ensures that the mutual information ($\rightarrow$ Definition I/2.4.1) is defined:

$$\mathrm{I}(X,Y) = \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x,y) \log \frac{p(x,y)}{p(x)\, p(y)}\, \mathrm{d}y\, \mathrm{d}x\ .$$

(2)

The relation of mutual information to conditional differential entropy ($\rightarrow$ Proof I/2.4.2) is:

$$\mathrm{I}(X,Y) = \mathrm{h}(X) - \mathrm{h}(X|Y)$$

(3)

$$\mathrm{I}(X,Y) = \mathrm{h}(Y) - \mathrm{h}(Y|X)$$

(4)

The relation of mutual information to joint differential entropy ($\rightarrow$ Proof I/2.4.3) is:

$$\mathrm{I}(X,Y) = \mathrm{h}(X) + \mathrm{h}(Y) - \mathrm{h}(X,Y)\ .$$

(5)

It is true that

$$\mathrm{I}(X,Y) = \mathrm{I}(X,Y) + \mathrm{I}(X,Y) - \mathrm{I}(X,Y)\ .$$

(6)

Plugging in (3), (4) and (5) on the right-hand side, we have

$$
\begin{aligned}
\mathrm{I}(X,Y) &= \mathrm{h}(X) - \mathrm{h}(X|Y) + \mathrm{h}(Y) - \mathrm{h}(Y|X) - \mathrm{h}(X) - \mathrm{h}(Y) + \mathrm{h}(X,Y) \\
&= \mathrm{h}(X,Y) - \mathrm{h}(X|Y) - \mathrm{h}(Y|X)
\end{aligned}
\tag{7}
$$

which proves the identity given above.

2.5 Kullback-Leibler divergence

2.5.1 Definition

Definition: Let X be a random variable ($\to$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let P and Q be two probability distributions ($\to$ Definition I/1.3.1) on X.
1) The Kullback-Leibler divergence of P from Q for a discrete random variable X is defined as

$$
\mathrm{KL}[P||Q] = \sum_{x \in \mathcal{X}} p(x) \cdot \log \frac{p(x)}{q(x)}
\tag{1}
$$

where $p(x)$ and $q(x)$ are the probability mass functions ($\to$ Definition I/1.4.1) of P and Q.
2) The Kullback-Leibler divergence of P from Q for a continuous random variable X is defined as

$$
\mathrm{KL}[P||Q] = \int_{\mathcal{X}} p(x) \cdot \log \frac{p(x)}{q(x)} \, \mathrm{d}x
\tag{2}
$$

where $p(x)$ and $q(x)$ are the probability density functions ($\to$ Definition I/1.4.4) of P and Q.

- MacKay, David J.C. (2003): "Probability, Entropy, and Inference"; in: *Information Theory, Inference, and Learning Algorithms*, ch. 2.6, eq. 2.45, p. 34; URL: https://www.inference.org.uk/itprnn/book.pdf.

Metadata: ID: D52 | shortcut: kl | author: JoramSoch | date: 2020-05-10, 20:20.

2.5.2 Non-negativity

Theorem: The Kullback-Leibler divergence ($\to$ Definition I/2.5.1) is always non-negative

$$
\mathrm{KL}[P||Q] \geq 0
\tag{1}
$$

with $\mathrm{KL}[P||Q] = 0$, if and only if $P = Q$.

Proof: The discrete Kullback-Leibler divergence ($\to$ Definition I/2.5.1) is defined as

$$\mathrm{KL}[P||Q] = \sum_{x \in \mathcal{X}} p(x) \cdot \log \frac{p(x)}{q(x)} \tag{2}$$

which can be reformulated into

$$\mathrm{KL}[P||Q] = \sum_{x \in \mathcal{X}} p(x) \cdot \log p(x) - \sum_{x \in \mathcal{X}} p(x) \cdot \log q(x) \ . \tag{3}$$

Gibbs' inequality ($\to$ Proof I/2.1.8) states that the entropy ($\to$ Definition I/2.1.1) of a probability distribution is always less than or equal to the cross-entropy ($\to$ Definition I/2.1.6) with another probability distribution – with equality only if the distributions are identical –,

$$-\sum_{i=1}^{n} p(x_i) \log p(x_i) \leq -\sum_{i=1}^{n} p(x_i) \log q(x_i) \tag{4}$$

which can be reformulated into

$$\sum_{i=1}^{n} p(x_i) \log p(x_i) - \sum_{i=1}^{n} p(x_i) \log q(x_i) \geq 0 \ . \tag{5}$$

Applying (5) to (3), this proves equation (1).

Sources:
- Wikipedia (2020): "Kullback-Leibler divergence"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-31; URL: https://en.wikipedia.org/wiki/Kullback%E2%80%93Leibler_divergence#Properties.

Metadata: ID: P117 | shortcut: kl-nonneg | author: JoramSoch | date: 2020-05-31, 23:43.

2.5.3   Non-negativity

Theorem: The Kullback-Leibler divergence ($\to$ Definition I/2.5.1) is always non-negative

$$\mathrm{KL}[P||Q] \geq 0 \tag{1}$$

with $\mathrm{KL}[P||Q] = 0$, if and only if $P = Q$.

Proof: The discrete Kullback-Leibler divergence ($\to$ Definition I/2.5.1) is defined as

$$\mathrm{KL}[P||Q] = \sum_{x \in \mathcal{X}} p(x) \cdot \log \frac{p(x)}{q(x)} \ . \tag{2}$$

The log sum inequality ($\to$ Proof I/2.1.9) states that

$$\sum_{i=1}^{n} a_i \log_c \frac{a_i}{b_i} \geq a \log_c \frac{a}{b} \ . \tag{3}$$

where $a_1, \ldots, a_n$ and $b_1, \ldots, b_n$ be non-negative real numbers and $a = \sum_{i=1}^{n} a_i$ and $b = \sum_{i=1}^{n} b_i$. Because $p(x)$ and $q(x)$ are probability mass functions ($\to$ Definition I/1.4.1), such that

$$p(x) \geq 0, \quad \sum_{x \in \mathcal{X}} p(x) = 1 \quad \text{and}$$

$$q(x) \geq 0, \quad \sum_{x \in \mathcal{X}} q(x) = 1 \; , \tag{4}$$

theorem (1) is simply a special case of (3), i.e.

$$\mathrm{KL}[P||Q] \overset{(2)}{=} \sum_{x \in \mathcal{X}} p(x) \cdot \log \frac{p(x)}{q(x)} \overset{(3)}{\geq} 1 \, \log \frac{1}{1} = 0 \; . \tag{5}$$

Sources:
- Wikipedia (2020): "Log sum inequality"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-09-09; URL: https://en.wikipedia.org/wiki/Log_sum_inequality#Applications.

Metadata: ID: P166 | shortcut: kl-nonneg2 | author: JoramSoch | date: 2020-09-09, 07:02.

2.5.4 Non-symmetry

Theorem: The Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) is non-symmetric, i.e.

$$\mathrm{KL}[P||Q] \neq \mathrm{KL}[Q||P] \tag{1}$$

for some probability distributions ($\rightarrow$ Definition I/1.3.1) P and Q.

Proof: Let $X \in \mathcal{X} = \{0, 1, 2\}$ be a discrete random variable ($\rightarrow$ Definition I/1.1.3) and consider the two probability distributions ($\rightarrow$ Definition I/1.3.1)

$$\begin{aligned} P &: \; X \sim \mathrm{Bin}(2, 0.5) \\ Q &: \; X \sim \mathcal{U}(0, 2) \end{aligned} \tag{2}$$

where $\mathrm{Bin}(n, p)$ indicates a binomial distribution ($\rightarrow$ Definition II/1.3.1) and $\mathcal{U}(a, b)$ indicates a discrete uniform distribution ($\rightarrow$ Definition II/1.1.1).
Then, the probability mass function of the binomial distribution ($\rightarrow$ Proof II/1.3.2) entails that

$$p(x) = \begin{cases} 1/4 \;, & \text{if } x = 0 \\ 1/2 \;, & \text{if } x = 1 \\ 1/4 \;, & \text{if } x = 2 \end{cases} \tag{3}$$

and the probability mass function of the discrete uniform distribution ($\rightarrow$ Proof II/1.1.2) entails that

$$q(x) = \frac{1}{3} \; , \tag{4}$$

such that the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) of P from Q is

$$
\begin{aligned}
\mathrm{KL}[P||Q] &= \sum_{x \in \mathcal{X}} p(x) \cdot \log \frac{p(x)}{q(x)} \\
&= \frac{1}{4} \log \frac{3}{4} + \frac{1}{2} \log \frac{3}{2} + \frac{1}{4} \log \frac{3}{4} \\
&= \frac{1}{2} \log \frac{3}{4} + \frac{1}{2} \log \frac{3}{2} \\
&= \frac{1}{2} \left(\log \frac{3}{4} + \log \frac{3}{2} \right) \\
&= \frac{1}{2} \log \left(\frac{3}{4} \cdot \frac{3}{2} \right) \\
&= \frac{1}{2} \log \frac{9}{8} = 0.0589
\end{aligned}
\tag{5}
$$

and the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) of Q from P is

$$
\begin{aligned}
\mathrm{KL}[Q||P] &= \sum_{x \in \mathcal{X}} q(x) \cdot \log \frac{q(x)}{p(x)} \\
&= \frac{1}{3} \log \frac{4}{3} + \frac{1}{3} \log \frac{2}{3} + \frac{1}{3} \log \frac{4}{3} \\
&= \frac{1}{3} \left(\log \frac{4}{3} + \log \frac{2}{3} + \log \frac{4}{3} \right) \\
&= \frac{1}{3} \log \left(\frac{4}{3} \cdot \frac{2}{3} \cdot \frac{4}{3} \right) \\
&= \frac{1}{3} \log \frac{32}{27} = 0.0566
\end{aligned}
\tag{6}
$$

which provides an example for

$$
\mathrm{KL}[P||Q] \neq \mathrm{KL}[Q||P] \tag{7}
$$

and thus proves the theorem.

Metadata: ID: P147 | shortcut: kl-nonsymm | author: JoramSoch | date: 2020-08-11, 06:57.

2.5.5 Convexity

Theorem: The Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) is convex in the pair of probability distributions ($\rightarrow$ Definition I/1.3.1) (p, q), i.e.

$$\mathrm{KL}[\lambda p_1 + (1-\lambda)p_2 || \lambda q_1 + (1-\lambda)q_2] \leq \lambda \mathrm{KL}[p_1||q_1] + (1-\lambda)\mathrm{KL}[p_2||q_2] \tag{1}$$

where (p_1, q_1) and (p_2, q_2) are two pairs of probability distributions and $0 \leq \lambda \leq 1$.

Proof: The Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) of P from Q is defined as

$$\mathrm{KL}[P||Q] = \sum_{x \in \mathcal{X}} p(x) \cdot \log \frac{p(x)}{q(x)} \tag{2}$$

and the log sum inequality ($\rightarrow$ Proof I/2.1.9) states that

$$\sum_{i=1}^{n} a_i \log \frac{a_i}{b_i} \geq \left(\sum_{i=1}^{n} a_i \right) \log \frac{\sum_{i=1}^{n} a_i}{\sum_{i=1}^{n} b_i} \tag{3}$$

where $a_1, \ldots, a_n$ and $b_1, \ldots, b_n$ are non-negative real numbers.
Thus, we can rewrite the KL divergence of the mixture distribution as

$$
\begin{aligned}
&\mathrm{KL}[\lambda p_1 + (1-\lambda)p_2 || \lambda q_1 + (1-\lambda)q_2] \\
&\overset{(2)}{=} \sum_{x \in \mathcal{X}} \left[[\lambda p_1(x) + (1-\lambda)p_2(x)] \cdot \log \frac{\lambda p_1(x) + (1-\lambda)p_2(x)}{\lambda q_1(x) + (1-\lambda)q_2(x)} \right] \\
&\overset{(3)}{\leq} \sum_{x \in \mathcal{X}} \left[\lambda p_1(x) \cdot \log \frac{\lambda p_1(x)}{\lambda q_1(x)} + (1-\lambda)p_2(x) \cdot \log \frac{(1-\lambda)p_2(x)}{(1-\lambda)q_2(x)} \right] \\
&= \lambda \sum_{x \in \mathcal{X}} p_1(x) \cdot \log \frac{p_1(x)}{q_1(x)} + (1-\lambda) \sum_{x \in \mathcal{X}} p_2(x) \cdot \log \frac{p_2(x)}{q_2(x)} \\
&\overset{(2)}{=} \lambda \, \mathrm{KL}[p_1||q_1] + (1-\lambda) \, \mathrm{KL}[p_2||q_2]
\end{aligned}
\tag{4}
$$

which is equivalent to (1).

2.5.6 Additivity for independent distributions

Theorem: The Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) is additive for independent distributions, i.e.

$$\mathrm{KL}[P||Q] = \mathrm{KL}[P_1||Q_1] + \mathrm{KL}[P_2||Q_2] \tag{1}$$

where P_1 and P_2 are independent ($\rightarrow$ Definition I/1.2.6) distributions ($\rightarrow$ Definition I/1.3.1) with the joint distribution ($\rightarrow$ Definition I/1.3.2) P, such that $p(x,y) = p_1(x)\,p_2(y)$, and equivalently for Q_1, Q_2 and Q.

Proof: The continuous Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) is defined as

$$\mathrm{KL}[P||Q] = \int_{\mathcal{X}} p(x) \cdot \log \frac{p(x)}{q(x)} \, \mathrm{d}x \tag{2}$$

which, applied to the joint distributions P and Q, yields

$$\mathrm{KL}[P||Q] = \int_{\mathcal{X}} \int_{\mathcal{Y}} p(x,y) \cdot \log \frac{p(x,y)}{q(x,y)} \, \mathrm{d}y \, \mathrm{d}x \; . \tag{3}$$

Applying $p(x,y) = p_1(x) \, p_2(y)$ and $q(x,y) = q_1(x) \, q_2(y)$, we have

$$\mathrm{KL}[P||Q] = \int_{\mathcal{X}} \int_{\mathcal{Y}} p_1(x) \, p_2(y) \cdot \log \frac{p_1(x) \, p_2(y)}{q_1(x) \, q_2(y)} \, \mathrm{d}y \, \mathrm{d}x \; . \tag{4}$$

Now we can separate the logarithm and evaluate the integrals:

$$
\begin{aligned}
\mathrm{KL}[P||Q] &= \int_{\mathcal{X}} \int_{\mathcal{Y}} p_1(x) \, p_2(y) \cdot \left(\log \frac{p_1(x)}{q_1(x)} + \log \frac{p_2(y)}{q_2(y)} \right) \, \mathrm{d}y \, \mathrm{d}x \\
&= \int_{\mathcal{X}} \int_{\mathcal{Y}} p_1(x) \, p_2(y) \cdot \log \frac{p_1(x)}{q_1(x)} \, \mathrm{d}y \, \mathrm{d}x + \int_{\mathcal{X}} \int_{\mathcal{Y}} p_1(x) \, p_2(y) \cdot \log \frac{p_2(y)}{q_2(y)} \, \mathrm{d}y \, \mathrm{d}x \\
&= \int_{\mathcal{X}} p_1(x) \cdot \log \frac{p_1(x)}{q_1(x)} \int_{\mathcal{Y}} p_2(y) \, \mathrm{d}y \, \mathrm{d}x + \int_{\mathcal{Y}} p_2(y) \cdot \log \frac{p_2(y)}{q_2(y)} \int_{\mathcal{X}} p_1(x) \, \mathrm{d}x \, \mathrm{d}y \\
&= \int_{\mathcal{X}} p_1(x) \cdot \log \frac{p_1(x)}{q_1(x)} \, \mathrm{d}x + \int_{\mathcal{Y}} p_2(y) \cdot \log \frac{p_2(y)}{q_2(y)} \, \mathrm{d}y \\
&\overset{(2)}{=} \mathrm{KL}[P_1||Q_1] + \mathrm{KL}[P_2||Q_2] \; .
\end{aligned}
\tag{5}
$$

2.5.7 Invariance under parameter transformation

Theorem: The Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) is invariant under parameter transformation, i.e.

$$\mathrm{KL}[p(x)||q(x)] = \mathrm{KL}[p(y)||q(y)] \tag{1}$$

where $y(x) = mx + n$ is an affine transformation of x and $p(x)$ and $q(x)$ are the probability density functions ($\rightarrow$ Definition I/1.4.4) of the probability distributions ($\rightarrow$ Definition I/1.3.1) P and Q on the continuous random variable ($\rightarrow$ Definition I/1.1.3) X.

Proof: The continuous Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) (KL divergence) is defined as

$$\mathrm{KL}[p(x)||q(x)] = \int_a^b p(x) \cdot \log \frac{p(x)}{q(x)} \, \mathrm{d}x \tag{2}$$

where $a = \min(\mathcal{X})$ and $b = \max(\mathcal{X})$ are the lower and upper bound of the possible outcomes $\mathcal{X}$ of X.

Due to the identity of the differentials

$$
\begin{aligned}
p(x)\,\mathrm{d}x &= p(y)\,\mathrm{d}y \\
q(x)\,\mathrm{d}x &= q(y)\,\mathrm{d}y
\end{aligned}
\tag{3}
$$

which can be rearranged into

$$
\begin{aligned}
p(x) &= p(y)\,\frac{\mathrm{d}y}{\mathrm{d}x} \\
q(x) &= q(y)\,\frac{\mathrm{d}y}{\mathrm{d}x}\ ,
\end{aligned}
\tag{4}
$$

the KL divergence can be evaluated as follows:

$$
\begin{aligned}
\mathrm{KL}[p(x)||q(x)] &= \int_a^b p(x) \cdot \log \frac{p(x)}{q(x)}\,\mathrm{d}x \\
&= \int_{y(a)}^{y(b)} p(y)\,\frac{\mathrm{d}y}{\mathrm{d}x} \cdot \log \left(\frac{p(y)\,\frac{\mathrm{d}y}{\mathrm{d}x}}{q(y)\,\frac{\mathrm{d}y}{\mathrm{d}x}} \right)\,\mathrm{d}x \\
&= \int_{y(a)}^{y(b)} p(y) \cdot \log \frac{p(y)}{q(y)}\,\mathrm{d}y \\
&= \mathrm{KL}[p(y)||q(y)]\ .
\end{aligned}
\tag{5}
$$

2.5.8 Relation to discrete entropy

Theorem: Let X be a discrete random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let P and Q be two probability distributions ($\rightarrow$ Definition I/1.3.1) on X. Then, the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) of P from Q can be expressed as

$$
\mathrm{KL}[P||Q] = \mathrm{H}(P, Q) - \mathrm{H}(P)
\tag{1}
$$

where $\mathrm{H}(P, Q)$ is the cross-entropy ($\rightarrow$ Definition I/2.1.6) of P and Q and $\mathrm{H}(P)$ is the marginal entropy ($\rightarrow$ Definition I/2.1.1) of P.

Proof: The discrete Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) is defined as

$$\mathrm{KL}[P||Q] = \sum_{x \in \mathcal{X}} p(x) \cdot \log \frac{p(x)}{q(x)} \tag{2}$$

where $p(x)$ and $q(x)$ are the probability mass functions ($\rightarrow$ Definition I/1.4.1) of P and Q. Separating the logarithm, we have:

$$\mathrm{KL}[P||Q] = -\sum_{x \in \mathcal{X}} p(x) \log q(x) + \sum_{x \in \mathcal{X}} p(x) \log p(x) \,. \tag{3}$$

Now considering the definitions of marginal entropy ($\rightarrow$ Definition I/2.1.1) and cross-entropy ($\rightarrow$ Definition I/2.1.6)

$$\begin{aligned}
\mathrm{H}(P) &= -\sum_{x \in \mathcal{X}} p(x) \log p(x) \\
\mathrm{H}(P, Q) &= -\sum_{x \in \mathcal{X}} p(x) \log q(x) \,,
\end{aligned} \tag{4}$$

we can finally show:

$$\mathrm{KL}[P||Q] = \mathrm{H}(P, Q) - \mathrm{H}(P) \,. \tag{5}$$

Sources:

2.5.9   Relation to differential entropy

Theorem: Let X be a continuous random variable ($\rightarrow$ Definition I/1.1.3) with possible outcomes $\mathcal{X}$ and let P and Q be two probability distributions ($\rightarrow$ Definition I/1.3.1) on X. Then, the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) of P from Q can be expressed as

$$\mathrm{KL}[P||Q] = \mathrm{h}(P, Q) - \mathrm{h}(P) \tag{1}$$

where $\mathrm{h}(P, Q)$ is the differential cross-entropy ($\rightarrow$ Definition I/2.2.7) of P and Q and $\mathrm{h}(P)$ is the marginal differential entropy ($\rightarrow$ Definition I/2.2.1) of P.

Proof: The continuous Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) is defined as

$$\mathrm{KL}[P||Q] = \int_{\mathcal{X}} p(x) \cdot \log \frac{p(x)}{q(x)} \, \mathrm{d}x \tag{2}$$

where $p(x)$ and $q(x)$ are the probability density functions ($\rightarrow$ Definition I/1.4.4) of P and Q. Separating the logarithm, we have:

$$\mathrm{KL}[P||Q] = -\int_{\mathcal{X}} p(x) \log q(x) \, \mathrm{d}x + \int_{\mathcal{X}} p(x) \log p(x) \, \mathrm{d}x \,. \tag{3}$$

Now considering the definitions of marginal differential entropy ($\rightarrow$ Definition I/2.2.1) and differential cross-entropy ($\rightarrow$ Definition I/2.2.7)

$$
\begin{aligned}
\mathrm{h}(P) &= -\int_{\mathcal{X}} p(x) \, \log p(x) \, \mathrm{d}x \\
\mathrm{h}(P,Q) &= -\int_{\mathcal{X}} p(x) \, \log q(x) \, \mathrm{d}x \; ,
\end{aligned}
\tag{4}
$$

we can finally show:

$$
\mathrm{KL}[P||Q] = \mathrm{h}(P,Q) - \mathrm{h}(P) \; .
\tag{5}
$$

3   Estimation theory

3.1   Point estimates

3.1.1   Partition of the mean squared error into bias and variance

Theorem: The mean squared error ($\to$ Definition "mse") can be partitioned into variance and squared bias

$$\mathrm{MSE}(\hat{\theta}) = \mathrm{Var}(\hat{\theta}) - \mathrm{Bias}(\hat{\theta}, \theta)^2 \tag{1}$$

where the variance ($\to$ Definition I/1.6.1) is given by

$$\mathrm{Var}(\hat{\theta}) = \mathbb{E}_{\hat{\theta}}\left[\left(\hat{\theta} - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) \right)^2 \right] \tag{2}$$

and the bias ($\to$ Definition "bias") is given by

$$\mathrm{Bias}(\hat{\theta}, \theta) = \left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right) . \tag{3}$$

Proof: The mean squared error (MSE) is defined as ($\to$ Definition "mse") the expected value ($\to$ Definition I/1.5.1) of the squared deviation of the estimated value $\hat{\theta}$ from the true value θ of a parameter, over all values $\hat{\theta}$:

$$\mathrm{MSE}(\hat{\theta}) = \mathbb{E}_{\hat{\theta}}\left[\left(\hat{\theta} - \theta \right)^2 \right] . \tag{4}$$

This formula can be evaluated in the following way:

$$\begin{aligned}
\mathrm{MSE}(\hat{\theta}) &= \mathbb{E}_{\hat{\theta}}\left[\left(\hat{\theta} - \theta \right)^2 \right] \\
&= \mathbb{E}_{\hat{\theta}}\left[\left(\hat{\theta} - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) + \mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right)^2 \right] \\
&= \mathbb{E}_{\hat{\theta}}\left[\left(\hat{\theta} - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) \right)^2 + 2 \left(\hat{\theta} - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) \right) \left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right) + \left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right)^2 \right] \\
&= \mathbb{E}_{\hat{\theta}}\left[\left(\hat{\theta} - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) \right)^2 \right] + \mathbb{E}_{\hat{\theta}}\left[2 \left(\hat{\theta} - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) \right) \left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right) \right] + \mathbb{E}_{\hat{\theta}}\left[\left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right)^2 \right] .
\end{aligned} \tag{5}$$

Because $\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta$ is constant as a function of $\hat{\theta}$, we have:

$$\begin{aligned}
\mathrm{MSE}(\hat{\theta}) &= \mathbb{E}_{\hat{\theta}}\left[\left(\hat{\theta} - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) \right)^2 \right] + 2 \left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right) \mathbb{E}_{\hat{\theta}}\left[\hat{\theta} - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) \right] + \left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right)^2 \\
&= \mathbb{E}_{\hat{\theta}}\left[\left(\hat{\theta} - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) \right)^2 \right] + 2 \left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right) \left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) \right) + \left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right)^2 \\
&= \mathbb{E}_{\hat{\theta}}\left[\left(\hat{\theta} - \mathbb{E}_{\hat{\theta}}(\hat{\theta}) \right)^2 \right] + \left(\mathbb{E}_{\hat{\theta}}(\hat{\theta}) - \theta \right)^2 .
\end{aligned} \tag{6}$$

This proofs the partition given by (1).

3.2 Interval estimates

3.2.1 Construction of confidence intervals using Wilks' theorem

Theorem: Let m be a generative model ($\to$ Definition I/5.1.1) for measured data y with model parameters θ, consisting of a parameter of interest ϕ and nuisance parameters λ:

$$m : p(y|\theta) = \mathcal{D}(y; \theta), \quad \theta = \{\phi, \lambda\} \ . \tag{1}$$

Further, let $\hat{\theta}$ be an estimate of θ, obtained using maximum-likelihood-estimation ($\to$ Definition I/4.1.3):

$$\hat{\theta} = \arg\max_{\theta} \log p(y|\theta), \quad \hat{\theta} = \left\{\hat{\phi}, \hat{\lambda}\right\} \ . \tag{2}$$

Then, an asymptotic confidence interval ($\to$ Definition "ci") for θ is given by

$$\mathrm{CI}_{1-\alpha}(\hat{\phi}) = \left\{\phi \mid \log p(y|\phi, \hat{\lambda}) \geq \log p(y|\hat{\phi}, \hat{\lambda}) - \frac{1}{2}\chi^2_{1, 1-\alpha}\right\} \tag{3}$$

where $1 - \alpha$ is the confidence level and $\chi^2_{1, 1-\alpha}$ is the $(1-\alpha)$-quantile of the chi-squared distribution ($\to$ Definition II/3.6.1) with 1 degree of freedom ($\to$ Definition "dof").

Proof: The confidence interval ($\to$ Definition "ci") is defined as the interval that, under infinitely repeated random experiments ($\to$ Definition I/1.1.1), contains the true parameter value with a certain probability.

Let us define the likelihood ratio ($\to$ Definition "lr")

$$\Lambda(\phi) = \frac{p(y|\phi, \hat{\lambda})}{p(y|\hat{\phi}, \hat{\lambda})} \tag{4}$$

and compute the log-likelihood ratio ($\to$ Definition "llr")

$$\log \Lambda(\phi) = \log p(y|\phi, \hat{\lambda}) - \log p(y|\hat{\phi}, \hat{\lambda}) \ . \tag{5}$$

Wilks' theorem ($\to$ Proof "llr-wilks") states that, when comparing two statistical models with parameter spaces Θ_1 and $\Theta_0 \subset \Theta_1$, as the sample size approaches infinity, the quantity calculated as -2 times the log-ratio of maximum likelihoods follows a chi-squared distribution ($\to$ Definition II/3.6.1), if the null hypothesis is true:

$$H_0 : \theta \in \Theta_0 \quad \Rightarrow \quad -2 \log \frac{\max_{\theta \in \Theta_0} p(y|\theta)}{\max_{\theta \in \Theta_1} p(y|\theta)} \sim \chi^2_{\Delta k} \tag{6}$$

where Δk is the difference in dimensionality between Θ_0 and Θ_1. Applied to our example in (5), we note that $\Theta_1 = \left\{\phi, \hat{\phi}\right\}$ and $\Theta_0 = \{\phi\}$, such that $\Delta k = 1$ and Wilks' theorem implies:

$$-2 \log \Lambda(\phi) \sim \chi_1^2 \;. \tag{7}$$

Using the quantile function ($\to$ Definition I/1.4.17) $\chi_{k,p}^2$ of the chi-squared distribution ($\to$ Definition II/3.6.1), an $(1 - \alpha)$-confidence interval is therefore given by all values ϕ that satisfy

$$-2 \log \Lambda(\phi) \leq \chi_{1,1-\alpha}^2 \;. \tag{8}$$

Applying (5) and rearranging, we can evaluate

$$
\begin{aligned}
-2 \left[\log p(y|\phi, \hat{\lambda}) - \log p(y|\hat{\phi}, \hat{\lambda}) \right] &\leq \chi_{1,1-\alpha}^2 \\
\log p(y|\phi, \hat{\lambda}) - \log p(y|\hat{\phi}, \hat{\lambda}) &\geq -\frac{1}{2} \chi_{1,1-\alpha}^2 \\
\log p(y|\phi, \hat{\lambda}) &\geq \log p(y|\hat{\phi}, \hat{\lambda}) - \frac{1}{2} \chi_{1,1-\alpha}^2
\end{aligned}
\tag{9}
$$

which is equivalent to the confidence interval given by (3).

4 Frequentist statistics

4.1 Likelihood theory

4.1.1 Likelihood function

Definition: Let there be a generative model ($\to$ Definition I/5.1.1) m describing measured data y using model parameters θ. Then, the probability density function ($\to$ Definition I/1.4.4) of the distribution of y given θ is called the likelihood function of m:

$$\mathcal{L}_m(\theta) = p(y|\theta, m) = \mathcal{D}(y; \theta) \; . \tag{1}$$

Sources:
- original work

Metadata: ID: D28 | shortcut: lf | author: JoramSoch | date: 2020-03-03, 15:50.

4.1.2 Log-likelihood function

Definition: Let there be a generative model ($\to$ Definition I/5.1.1) m describing measured data y using model parameters θ. Then, the logarithm of the probability density function ($\to$ Definition I/1.4.4) of the distribution of y given θ is called the log-likelihood function ($\to$ Definition I/5.1.2) of m:

$$\mathrm{LL}_m(\theta) = \log p(y|\theta, m) = \log \mathcal{D}(y; \theta) \; . \tag{1}$$

Sources:
- original work

Metadata: ID: D59 | shortcut: llf | author: JoramSoch | date: 2020-05-17, 22:52.

4.1.3 Maximum likelihood estimation

Definition: Let there be a generative model ($\to$ Definition I/5.1.1) m describing measured data y using model parameters θ. Then, the parameter values maximizing the likelihood function ($\to$ Definition I/5.1.2) or log-likelihood function ($\to$ Definition I/4.1.2) are called maximum likelihood estimates of θ:

$$\hat{\theta} = \arg\max_{\theta} \mathcal{L}_m(\theta) = \arg\max_{\theta} \mathrm{LL}_m(\theta) \; . \tag{1}$$

The process of calculating $\hat{\theta}$ is called "maximum likelihood estimation" and the functional form leading from y to $\hat{\theta}$ given m is called "maximum likelihood estimator". Maximum likelihood estimation, estimator and estimates may all be abbreviated as "MLE".

Sources:
- original work

Metadata: ID: D60 | shortcut: mle | author: JoramSoch | date: 2020-05-15, 23:05.

4.1.4 Maximum log-likelihood

Definition: Let there be a generative model ($\to$ Definition I/5.1.1) m describing measured data y using model parameters θ. Then, the maximum log-likelihood (MLL) of m is the maximal value of the log-likelihood function ($\to$ Definition I/4.1.2) of this model:

$$\mathrm{MLL}(m) = \max_{\theta} \mathrm{LL}_m(\theta) \,. \tag{1}$$

The maximum log-likelihood can be obtained by plugging the maximum likelihood estimates ($\to$ Definition I/4.1.3) into the log-likelihood function ($\to$ Definition I/4.1.2).

Sources:

- original work

Metadata: ID: D61 | shortcut: mll | author: JoramSoch | date: 2020-05-15, 23:13.

4.1.5 Method of moments

Definition: Let measured data y follow a probability distribution ($\to$ Definition I/1.3.1) with probability mass ($\to$ Definition I/1.4.1) or probability density ($\to$ Definition I/1.4.4) $p(y|\theta)$ governed by unknown parameters $\theta_1, \ldots, \theta_k$. Then, method-of-moments estimation, also referred to as "method of moments" or "matching the moments", consists in

1) expressing the first k moments ($\to$ Definition I/1.12.1) of y in terms of θ

$$\begin{aligned}
\mu_1 &= f_1(\theta_1, \ldots, \theta_k) \\
&\vdots \\
\mu_k &= f_k(\theta_1, \ldots, \theta_k) \,,
\end{aligned} \tag{1}$$

2) calculating the first k sample moments ($\to$ Definition I/1.12.1) from y

$$\hat{\mu}_1(y), \ldots, \hat{\mu}_k(y) \tag{2}$$

3) and solving the system of k equations

$$\begin{aligned}
\hat{\mu}_1(y) &= f_1(\hat{\theta}_1, \ldots, \hat{\theta}_k) \\
&\vdots \\
\hat{\mu}_k(y) &= f_k(\hat{\theta}_1, \ldots, \hat{\theta}_k)
\end{aligned} \tag{3}$$

for $\hat{\theta}_1, \ldots, \hat{\theta}_k$, which are subsequently refered to as "method-of-moments estimates".

4.2 Statistical hypotheses

4.2.1 Statistical hypothesis

Definition: A statistical hypothesis is a statement about the parameters of a distribution describing a population from which observations can be sampled as measured data ($\to$ Definition "data").
More precisely, let m be a generative model ($\to$ Definition I/5.1.1) describing measured data y in terms of a distribution $\mathcal{D}(\theta)$ with model parameters $\theta \in \Theta$. Then, a statistical hypothesis is formally specified as

$$H : \ \theta \in \Theta^* \quad \text{where} \quad \Theta^* \subset \Theta \ . \tag{1}$$

Sources:
- Wikipedia (2021): "Statistical hypothesis testing"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-19; URL: https://en.wikipedia.org/wiki/Statistical_hypothesis_testing#Definition_of_terms.

Metadata: ID: D127 | shortcut: hyp | author: JoramSoch | date: 2021-03-19, 14:18.

4.2.2 Simple vs. composite

Definition: Let H be a statistical hypothesis ($\to$ Definition I/4.2.1). Then,
- H is called a simple hypothesis, if it completely specifies the population distribution; in this case, the sampling distribution ($\to$ Definition I/1.3.5) of the test statistic ($\to$ Definition I/4.3.5) is a function of sample size alone.
- H is called a composite hypothesis, if it does not completely specify the population distribution; for example, the hypothesis may only specify one parameter of the distribution and leave others unspecified.

Sources:
- Wikipedia (2021): "Exclusion of the null hypothesis"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-19; URL: https://en.wikipedia.org/wiki/Exclusion_of_the_null_hypothesis#Terminology.

Metadata: ID: D128 | shortcut: hyp-simp | author: JoramSoch | date: 2021-03-19, 14:24.

4.2.3 Point/exact vs. set/inexact

Definition: Let H be a statistical hypothesis ($\to$ Definition I/4.2.1). Then,
- H is called a point hypothesis or exact hypothesis, if it specifies an exact parameter value:

$$H : \ \theta = \theta^* \ ; \tag{1}$$

- H is called a set hypothesis or inexact hypothesis, if it specifies a set of possible values with more than one element for the parameter value (e.g. a range or an interval):

$$H : \; \theta \in \Theta^* \; . \tag{2}$$

Sources:
- Wikipedia (2021): "Exclusion of the null hypothesis"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-19; URL: https://en.wikipedia.org/wiki/Exclusion_of_the_null_hypothesis#Terminology.

Metadata: ID: D129 | shortcut: hyp-point | author: JoramSoch | date: 2021-03-19, 14:28.

4.2.4 One-tailed vs. two-tailed

Definition: Let H_0 be a point ($\rightarrow$ Definition I/4.2.3) null hypothesis ($\rightarrow$ Definition I/4.3.2)

$$H_0 : \; \theta = \theta_0 \tag{1}$$

and consider a set ($\rightarrow$ Definition I/4.2.3) alternative hypothesis ($\rightarrow$ Definition I/4.3.3) H_1. Then,
- H_1 is called a left-sided one-tailed hypothesis, if θ is assumed to be smaller than θ_0:

$$H_1 : \; \theta < \theta_0 \; ; \tag{2}$$

- H_1 is called a right-sided one-tailed hypothesis, if θ is assumed to be larger than θ_0:

$$H_1 : \; \theta > \theta_0 \; ; \tag{3}$$

- H_1 is called a two-tailed hypothesis, if θ is assumed to be unequal to θ_0:

$$H_1 : \; \theta \neq \theta_0 \; . \tag{4}$$

Sources:
- Wikipedia (2021): "One- and two-tailed tests"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-31; URL: https://en.wikipedia.org/wiki/One-_and_two-tailed_tests.

Metadata: ID: D138 | shortcut: hyp-tail | author: JoramSoch | date: 2021-03-31, 09:21.

4.3 Hypothesis testing

4.3.1 Statistical test

Definition: Let y be a set of measured data ($\rightarrow$ Definition "data"). Then, a statistical hypothesis test consists of the following:
- an assumption about the distribution ($\rightarrow$ Definition I/1.3.1) of the data, often expressed in terms of a statistical model ($\rightarrow$ Definition I/5.1.1) m;
- a null hypothesis ($\rightarrow$ Definition I/4.3.2) H_0 and an alternative hypothesis ($\rightarrow$ Definition I/4.3.3) H_1 which make specific statements about the distribution of the data;
- a test statistic ($\rightarrow$ Definition I/4.3.5) $T(Y)$ which is a function of the data and whose distribution under the null hypothesis ($\rightarrow$ Definition I/4.3.2) is known;

- a significance level ($\to$ Definition I/4.3.8) α which imposes an upper bound on the probability ($\to$ Definition I/1.2.1) of rejecting H_0, given that H_0 is true.

Procedurally, the statistical hypothesis test works as follows:

- Given the null hypothesis H_0 and the significance level α, a critical value ($\to$ Definition I/4.3.9) t_{crit} is determined which partitions the set of possible values of $T(Y)$ into "acceptance region" and "rejection region".
- Then, the observed test statistic ($\to$ Definition I/4.3.5) $t_{\mathrm{obs}} = T(y)$ is calculated from the actually measured data y. If it is in the rejection region, H_0 is rejected in favor of H_1. Otherwise, the test fails to reject H_0.

Sources:

- Wikipedia (2021): "Statistical hypothesis testing"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-19; URL: https://en.wikipedia.org/wiki/Statistical_hypothesis_testing#The_testing_process.

Metadata: ID: D130 | shortcut: test | author: JoramSoch | date: 2021-03-19, 14:36.

4.3.2 Null hypothesis

Definition: The statement which is tested in a statistical hypothesis test ($\to$ Definition I/4.3.1) is called the "null hypothesis", denoted as H_0. The test is designed to assess the strength of evidence against H_0 and possibly reject it. The opposite of H_0 is called the "alternative hypothesis ($\to$ Definition I/4.3.3)". Usually, H_0 is a statement that a particular parameter is zero, that there is no effect of a particular treatment or that there is no difference between particular conditions.

More precisely, let m be a generative model ($\to$ Definition I/5.1.1) describing measured data y using model parameters $\theta \in \Theta$. Then, a null hypothesis is formally specified as

$$H_0 : \; \theta \in \Theta_0 \quad \text{where} \quad \Theta_0 \subset \Theta \; . \tag{1}$$

4.3.3 Alternative hypothesis

Definition: Let H_0 be a null hypothesis ($\to$ Definition I/4.3.2) of a statistical hypothesis test ($\to$ Definition I/4.3.1). Then, the corresponding alternative hypothesis, denoted as H_1, is either the negation of H_0 or an interesting sub-case in the negation of H_0, depending on context. The test is designed to assess the strength of evidence against H_0 and possibly reject it in favor of H_1. Usually, H_1 is a statement that a particular parameter is non-zero, that there is an effect of a particular treatment or that there is a difference between particular conditions.

More precisely, let m be a generative model ($\to$ Definition I/5.1.1) describing measured data y using model parameters $\theta \in \Theta$. Then, null and alternative hypothesis are formally specified as

$$\begin{aligned} H_0 : \; & \theta \in \Theta_0 \quad \text{where} \quad \Theta_0 \subset \Theta \\ H_1 : \; & \theta \in \Theta_1 \quad \text{where} \quad \Theta_1 = \Theta \setminus \Theta_0 \; . \end{aligned} \tag{1}$$

Sources:
- Wikipedia (2021): "Exclusion of the null hypothesis"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-12; URL: https://en.wikipedia.org/wiki/Exclusion_of_the_null_hypothesis#Basic_definitions.

Metadata: ID: D126 | shortcut: h1 | author: JoramSoch | date: 2021-03-12, 10:36.

4.3.4   One-tailed vs. two-tailed

Definition: Let there be a statistical test ($\rightarrow$ Definition I/4.3.1) of an alternative hypothesis ($\rightarrow$ Definition I/4.3.3) H_1 against a null hypothesis ($\rightarrow$ Definition I/4.3.2) H_0. Then,
- the test is called a one-tailed test, if H_1 is a one-tailed hypothesis ($\rightarrow$ Definition I/4.2.4);
- the test is called a two-tailed test, if H_1 is a two-tailed hypothesis ($\rightarrow$ Definition I/4.2.4).

The fact whether a test ($\rightarrow$ Definition I/4.3.1) is one-tailed or two-tailed has consequences for the computation of critical value ($\rightarrow$ Definition I/4.3.9) and p-value ($\rightarrow$ Definition I/4.3.10).

Sources:
- Wikipedia (2021): "One- and two-tailed tests"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-31; URL: https://en.wikipedia.org/wiki/One-_and_two-tailed_tests.

Metadata: ID: D139 | shortcut: test-tail | author: JoramSoch | date: 2021-03-31, 09:32.

4.3.5   Test statistic

Definition: In a statistical hypothesis test ($\rightarrow$ Definition I/4.3.1), the test statistic $T(Y)$ is a scalar function of the measured data ($\rightarrow$ Definition "data") y whose distribution under the null hypothesis ($\rightarrow$ Definition I/4.3.2) H_0 can be established. Together with a significance level ($\rightarrow$ Definition I/4.3.8) α, this distribution implies a critical value ($\rightarrow$ Definition I/4.3.9) t_{crit} of the test statistic which determines whether the test rejects or fails to reject H_0.

Sources:
- Wikipedia (2021): "Statistical hypothesis testing"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-19; URL: https://en.wikipedia.org/wiki/Statistical_hypothesis_testing#The_testing_process.

Metadata: ID: D131 | shortcut: tstat | author: JoramSoch | date: 2021-03-19, 14:40.

4.3.6   Size of a test

Definition: Let there be a statistical hypothesis test ($\rightarrow$ Definition I/4.3.1) with null hypothesis ($\rightarrow$ Definition I/4.3.2) H_0. Then, the size of the test is the probability of a false-positive result or

making a type I error, i.e. the probability ($\rightarrow$ Definition I/1.2.1) of rejecting the null hypothesis ($\rightarrow$ Definition I/4.3.2) H_0, given that H_0 is actually true.

For a simple null hypothesis ($\rightarrow$ Definition I/4.2.2), the size is determined by the following conditional probability ($\rightarrow$ Definition I/1.2.4):

$$\Pr(\text{test rejects } H_0 | H_0) \, . \tag{1}$$

For a composite null hypothesis ($\rightarrow$ Definition I/4.2.2), the size is the supremum over all possible realizations of the null hypothesis ($\rightarrow$ Definition I/4.3.2):

$$\sup_{h \in H_0} \Pr(\text{test rejects } H_0 | h) \, . \tag{2}$$

Sources:
- Wikipedia (2021): "Size (statistics)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-19; URL: https://en.wikipedia.org/wiki/Size_(statistics).

Metadata: ID: D132 | shortcut: size | author: JoramSoch | date: 2021-03-19, 14:46.

4.3.7 Power of a test

Definition: Let there be a statistical hypothesis test ($\rightarrow$ Definition I/4.3.1) with null hypothesis ($\rightarrow$ Definition I/4.3.2) H_0 and alternative hypothesis ($\rightarrow$ Definition I/4.3.3) H_1. Then, the power of the test is the probability of a true-positive result or not making a type II error, i.e. the probability ($\rightarrow$ Definition I/1.2.1) of rejecting H_0, given that H_1 is actually true.

For given null ($\rightarrow$ Definition I/4.3.2) and alternative ($\rightarrow$ Definition I/4.3.3) hypothesis ($\rightarrow$ Definition I/4.2.1), the size is determined by the following conditional probability ($\rightarrow$ Definition I/1.2.4):

$$\Pr(\text{test rejects } H_0 | H_1) \, . \tag{1}$$

Sources:
- Wikipedia (2021): "Power of a test"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-31; URL: https://en.wikipedia.org/wiki/Power_of_a_test#Description.

Metadata: ID: D137 | shortcut: power | author: JoramSoch | date: 2021-03-31, 09:01.

4.3.8 Significance level

Definition: Let the size ($\rightarrow$ Definition I/4.3.6) of a statistical hypothesis test ($\rightarrow$ Definition I/4.3.1) be the probability of a false-positive result or making a type I error, i.e. the probability ($\rightarrow$ Definition I/1.2.1) of rejecting the null hypothesis ($\rightarrow$ Definition I/4.3.2) H_0, given that H_0 is actually true:

$$\Pr(\text{test rejects } H_0 | H_0) \, . \tag{1}$$

Then, the test is said to have significance level α, if the size is less than or equal to α:

$$\Pr(\text{test rejects } H_0 | H_0) \leq \alpha \, . \tag{2}$$

Sources:

- Wikipedia (2021): "Statistical hypothesis testing"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-19; URL: https://en.wikipedia.org/wiki/Statistical_hypothesis_testing#Definition_of_terms.

Metadata: ID: D133 | shortcut: alpha | author: JoramSoch | date: 2021-03-19, 14:50.

4.3.9   Critical value

Definition: In a statistical hypothesis test ($\to$ Definition I/4.3.1), the critical value ($\to$ Definition I/4.3.9) t_{crit} is that value of the test statistic ($\to$ Definition I/4.3.5) $T(Y)$ which partitions the set of possible test statistics into "acceptance region" and "rejection region" based on a significance level ($\to$ Definition I/4.3.8) α. Put differently, if the observed test statistic $t_{\mathrm{obs}} = T(y)$ computed from actually measured data ($\to$ Definition "data") y is as extreme or more extreme than the critical value, the test rejects the null hypothesis ($\to$ Definition I/4.3.2) H_0 in favor of the alternative hypothesis ($\to$ Definition I/4.3.3).

Sources:
- Wikipedia (2021): "Statistical hypothesis testing"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-19; URL: https://en.wikipedia.org/wiki/Statistical_hypothesis_testing#Definition_of_terms.

Metadata: ID: D134 | shortcut: cval | author: JoramSoch | date: 2021-03-19, 14:54.

4.3.10   p-value

Definition: Let there be a statistical test ($\to$ Definition I/4.3.1) of the null hypothesis ($\to$ Definition I/4.3.2) H_0 and the alternative hypothesis ($\to$ Definition I/4.3.3) H_1 using the test statistic ($\to$ Definition I/4.3.5) $T(Y)$. Let y be the measured data ($\to$ Definition "data") and let $t_{\mathrm{obs}} = T(y)$ be the observed test statistic computed from y. Moreover, assume that $F_T(t)$ is the cumulative distribution function ($\to$ Definition I/1.4.8) (CDF) of the distribution of $T(Y)$ under H_0.

Then, the p-value is the probability of obtaining a test statistic more extreme than or as extreme as t_{obs}, given that the null hypothesis H_0 is true:

- $p = F_T^{-1}(t_{\mathrm{obs}})$, if H_1 is a left-sided one-tailed hypothesis ($\to$ Definition I/4.2.4);
- $p = 1 - F_T^{-1}(t_{\mathrm{obs}})$, if H_1 is a right-sided one-tailed hypothesis ($\to$ Definition I/4.2.4);
- $p = 2 \cdot \min\left(\left[F_T^{-1}(t_{\mathrm{obs}}),\, 1 - F_T^{-1}(t_{\mathrm{obs}})\right]\right)$, if H_1 is a two-tailed hypothesis ($\to$ Definition I/4.2.4).

5 Bayesian statistics

5.1 Probabilistic modeling

5.1.1 Generative model

Definition: Consider measured data y and some unknown latent parameters θ. A statement about the distribution of y given θ is called a generative model m:

$$m : y \sim \mathcal{D}(\theta) . \tag{1}$$

Sources:
- original work

Metadata: ID: D27 | shortcut: gm | author: JoramSoch | date: 2020-03-03, 15:50.

5.1.2 Likelihood function

Definition: Let there be a generative model ($\rightarrow$ Definition I/5.1.1) m describing measured data y using model parameters θ. Then, the probability density function ($\rightarrow$ Definition I/1.4.4) of the distribution of y given θ is called the likelihood function of m:

$$\mathcal{L}_m(\theta) = p(y|\theta, m) = \mathcal{D}(y; \theta) . \tag{1}$$

Sources:
- original work

Metadata: ID: D28 | shortcut: lf | author: JoramSoch | date: 2020-03-03, 15:50.

5.1.3 Prior distribution

Definition: Consider measured data y and some unknown latent parameters θ. A distribution of θ unconditional on y is called a prior distribution:

$$\theta \sim \mathcal{D}(\lambda) . \tag{1}$$

The parameters λ of this distribution are called the prior hyperparameters and the probability density function ($\rightarrow$ Definition I/1.4.4) is called the prior density:

$$p(\theta|m) = \mathcal{D}(\theta; \lambda) . \tag{2}$$

Sources:
- original work

Metadata: ID: D29 | shortcut: prior | author: JoramSoch | date: 2020-03-03, 16:09.

5.1.4 Full probability model

Definition: Consider measured data y and some unknown latent parameters θ. The combination of a generative model ($\rightarrow$ Definition I/5.1.1) for y and a prior distribution ($\rightarrow$ Definition I/5.1.3) on θ is called a full probability model m:

$$m : y \sim \mathcal{D}(\theta), \ \theta \sim \mathcal{D}(\lambda) \,. \tag{1}$$

Sources:
- original work

Metadata: ID: D30 | shortcut: fpm | author: JoramSoch | date: 2020-03-03, 16:16.

5.1.5 Joint likelihood

Definition: Let there be a generative model ($\rightarrow$ Definition I/5.1.1) m describing measured data y using model parameters θ and a prior distribution ($\rightarrow$ Definition I/5.1.3) on θ. Then, the joint probability ($\rightarrow$ Definition I/1.2.2) density function ($\rightarrow$ Definition I/1.4.4) of y and θ is called the joint likelihood:

$$p(y, \theta | m) = p(y | \theta, m) \, p(\theta | m) \,. \tag{1}$$

Sources:
- original work

Metadata: ID: D31 | shortcut: jl | author: JoramSoch | date: 2020-03-03, 16:36.

5.1.6 Joint likelihood is product of likelihood and prior

Theorem: Let there be a generative model ($\rightarrow$ Definition I/5.1.1) m describing measured data y using model parameters θ and a prior distribution ($\rightarrow$ Definition I/5.1.3) on θ. Then, the joint likelihood ($\rightarrow$ Definition I/5.1.5) is equal to the product of likelihood function ($\rightarrow$ Definition I/5.1.2) and prior density ($\rightarrow$ Definition I/5.1.3):

$$p(y, \theta | m) = p(y | \theta, m) \, p(\theta | m) \,. \tag{1}$$

Proof: The joint likelihood ($\rightarrow$ Definition I/5.1.5) is defined as the joint probability ($\rightarrow$ Definition I/1.2.2) density function ($\rightarrow$ Definition I/1.4.4) of data y and parameters θ:

$$p(y, \theta | m) \,. \tag{2}$$

Applying the law of conditional probability ($\rightarrow$ Definition I/1.2.4), we have:

$$
\begin{aligned}
p(y | \theta, m) &= \frac{p(y, \theta | m)}{p(\theta | m)} \\
&\Leftrightarrow \\
p(y, \theta | m) &= p(y | \theta, m) \, p(\theta | m) \,.
\end{aligned}
\tag{3}
$$

Sources:
- original work

Metadata: ID: P89 | shortcut: jl-lfnprior | author: JoramSoch | date: 2020-05-05, 04:21.

5.1.7 Posterior distribution

Definition: Consider measured data y and some unknown latent parameters θ. The distribution of θ conditional on y is called the posterior distribution:

$$\theta|y \sim \mathcal{D}(\phi) \ . \tag{1}$$

The parameters ϕ of this distribution are called the posterior hyperparameters and the probability density function ($\rightarrow$ Definition I/1.4.4) is called the posterior density:

$$p(\theta|y, m) = \mathcal{D}(\theta; \phi) \ . \tag{2}$$

Sources:
- original work

Metadata: ID: D32 | shortcut: post | author: JoramSoch | date: 2020-03-03, 16:43.

5.1.8 Posterior density is proportional to joint likelihood

Theorem: In a full probability model ($\rightarrow$ Definition I/5.1.4) m describing measured data y using model parameters θ, the posterior density ($\rightarrow$ Definition I/5.1.7) over the model parameters is proportional to the joint likelihood ($\rightarrow$ Definition I/5.1.5):

$$p(\theta|y, m) \propto p(y, \theta|m) \ . \tag{1}$$

Proof: In a full probability model ($\rightarrow$ Definition I/5.1.4), the posterior distribution ($\rightarrow$ Definition I/5.1.7) can be expressed using Bayes' theorem ($\rightarrow$ Proof I/5.3.1):

$$p(\theta|y, m) = \frac{p(y|\theta, m) \, p(\theta|m)}{p(y|m)} \ . \tag{2}$$

Applying the law of conditional probability ($\rightarrow$ Definition I/1.2.4) to the numerator, we have:

$$p(\theta|y, m) = \frac{p(y, \theta|m)}{p(y|m)} \ . \tag{3}$$

Because the denominator does not depend on θ, it is constant in θ and thus acts a proportionality factor between the posterior distribution and the joint likelihood:

$$p(\theta|y, m) \propto p(y, \theta|m) \ . \tag{4}$$

Sources:
- original work

Metadata: ID: P90 | shortcut: post-jl | author: JoramSoch | date: 2020-05-05, 04:46.

5.1.9 Marginal likelihood

Definition: Let there be a generative model ($\rightarrow$ Definition I/5.1.1) m describing measured data y using model parameters θ and a prior distribution ($\rightarrow$ Definition I/5.1.3) on θ. Then, the marginal probability ($\rightarrow$ Definition I/1.2.3) density function ($\rightarrow$ Definition I/1.4.4) of y across the parameter space Θ is called the marginal likelihood:

$$p(y|m) = \int_\Theta p(y|\theta, m)\, p(\theta|m)\, \mathrm{d}\theta \; . \tag{1}$$

Sources:
- original work

Metadata: ID: D33 | shortcut: ml | author: JoramSoch | date: 2020-03-03, 16:49.

5.1.10 Marginal likelihood is integral of joint likelihood

Theorem: In a full probability model ($\rightarrow$ Definition I/5.1.4) m describing measured data y using model parameters θ, the marginal likelihood ($\rightarrow$ Definition I/5.1.9) is the integral of the joint likelihood ($\rightarrow$ Definition I/5.1.5) across the parameter space Θ:

$$p(y|m) = \int_\Theta p(y, \theta|m)\, \mathrm{d}\theta \; . \tag{1}$$

Proof: In a full probability model ($\rightarrow$ Definition I/5.1.4), the marginal likelihood ($\rightarrow$ Definition I/5.1.9) is defined as the marginal probability ($\rightarrow$ Definition I/1.2.3) of the data y, given only the model m:

$$p(y|m) \; . \tag{2}$$

Using the law of marginal probabililty ($\rightarrow$ Definition I/1.2.3), this can be obtained by integrating the joint likelihood ($\rightarrow$ Definition I/5.1.5) function over the entire parameter space:

$$p(y|m) = \int_\Theta p(y, \theta|m)\, \mathrm{d}\theta \; . \tag{3}$$

Applying the law of conditional probability ($\rightarrow$ Definition I/1.2.4), the integrand can also be written as the product of likelihood function ($\rightarrow$ Definition I/5.1.2) and prior density ($\rightarrow$ Definition I/5.1.3):

$$p(y|m) = \int_\Theta p(y|\theta, m)\, p(\theta|m)\, \mathrm{d}\theta \; . \tag{4}$$

Sources:
- original work

Metadata: ID: P91 | shortcut: ml-jl | author: JoramSoch | date: 2020-05-05, 04:59.

5.2 Prior distributions

5.2.1 Flat vs. hard vs. soft

Definition: Let $p(\theta|m)$ be a prior distribution ($\rightarrow$ Definition I/5.1.3) for the parameter θ of a generative model ($\rightarrow$ Definition I/5.1.1) m. Then,
- the distribution is called a "flat prior", if its precision ($\rightarrow$ Definition I/1.6.11) is zero or variance ($\rightarrow$ Definition I/1.6.1) is infinite;
- the distribution is called a "hard prior", if its precision ($\rightarrow$ Definition I/1.6.11) is infinite or variance ($\rightarrow$ Definition I/1.6.1) is zero;
- the distribution is called a "soft prior", if its precision ($\rightarrow$ Definition I/1.6.11) and variance ($\rightarrow$ Definition I/1.6.1) are non-zero and finite.

Metadata: ID: D116 | shortcut: prior-flat | author: JoramSoch | date: 2020-12-02, 17:04.

5.2.2 Uniform vs. non-uniform

Definition: Let $p(\theta|m)$ be a prior distribution ($\rightarrow$ Definition I/5.1.3) for the parameter θ of a generative model ($\rightarrow$ Definition I/5.1.1) m where θ belongs to the parameter space Θ. Then,
- the distribution is called a "uniform prior", if its density ($\rightarrow$ Definition I/1.4.4) or mass ($\rightarrow$ Definition I/1.4.1) is constant over Θ;
- the distribution is called a "non-uniform prior", if its density ($\rightarrow$ Definition I/1.4.4) or mass ($\rightarrow$ Definition I/1.4.1) is not constant over Θ.

Sources:
- Wikipedia (2020): "Lindley's paradox"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-11-25; URL: https://en.wikipedia.org/wiki/Lindley%27s_paradox#Bayesian_approach.

Metadata: ID: D117 | shortcut: prior-uni | author: JoramSoch | date: 2020-12-02, 17:21.

5.2.3 Informative vs. non-informative

Definition: Let $p(\theta|m)$ be a prior distribution ($\rightarrow$ Definition I/5.1.3) for the parameter θ of a generative model ($\rightarrow$ Definition I/5.1.1) m. Then,
- the distribution is called an "informative prior", if it biases the parameter towards particular values;
- the distribution is called a "weakly informative prior", if it mildly influences the posterior distribution ($\rightarrow$ Proof I/5.1.8);
- the distribution is called a "non-informative prior", if it does not influence ($\rightarrow$ Proof I/5.1.8) the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7).

Sources:
- Soch J, Allefeld C, Haynes JD (2016): "How to avoid mismodelling in GLM-based fMRI data analysis: cross-validated Bayesian model selection"; in: *NeuroImage*, vol. 141, pp. 469-489, eq. 15, p. 473; URL: https://www.sciencedirect.com/science/article/pii/S1053811916303615; DOI: 10.1016/j.neuroimage.2016.07.047.

Metadata: ID: D118 | shortcut: prior-inf | author: JoramSoch | date: 2020-12-02, 17:28.

5.2.4 Empirical vs. non-empirical

Definition: Let $p(\theta|m)$ be a prior distribution ($\rightarrow$ Definition I/5.1.3) for the parameter θ of a generative model ($\rightarrow$ Definition I/5.1.1) m. Then,
- the distribution is called an "empirical prior", if it has been derived from empirical data ($\rightarrow$ Proof I/5.1.8);
- the distribution is called a "theoretical prior", if it was specified without regard to empirical data.

Sources:
- Soch J, Allefeld C, Haynes JD (2016): "How to avoid mismodelling in GLM-based fMRI data analysis: cross-validated Bayesian model selection"; in: *NeuroImage*, vol. 141, pp. 469-489, eq. 13, p. 473; URL: https://www.sciencedirect.com/science/article/pii/S1053811916303615; DOI: 10.1016/j.neuroimage.2016.07.047.

Metadata: ID: D119 | shortcut: prior-emp | author: JoramSoch | date: 2020-12-02, 17:37.

5.2.5 Conjugate vs. non-conjugate

Definition: Let m be a generative model ($\rightarrow$ Definition I/5.1.1) with likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, m)$ and prior distribution ($\rightarrow$ Definition I/5.1.3) $p(\theta|m)$. Then,
- the prior distribution ($\rightarrow$ Definition I/5.1.3) is called "conjugate", if it, when combined with the likelihood function ($\rightarrow$ Definition I/5.1.2), leads to a posterior distribution ($\rightarrow$ Definition I/5.1.7) that belongs to the same family of probability distributions ($\rightarrow$ Definition I/1.3.1);
- the prior distribution is called "non-conjugate", if this is not the case.

Sources:
- Wikipedia (2020): "Conjugate prior"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-12-02; URL: https://en.wikipedia.org/wiki/Conjugate_prior.

Metadata: ID: D120 | shortcut: prior-conj | author: JoramSoch | date: 2020-12-02, 17:55.

5.2.6 Maximum entropy priors

Definition: Let m be a generative model ($\rightarrow$ Definition I/5.1.1) with likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, m)$ and prior distribution ($\rightarrow$ Definition I/5.1.3) $p(\theta|\lambda, m)$ using prior hyperparameters ($\rightarrow$ Definition I/5.1.3) λ. Then, the prior distribution is called a "maximum entropy prior", if
1) when θ is a discrete random variable ($\rightarrow$ Definition I/1.1.7), it maximizes the entropy ($\rightarrow$ Definition I/2.1.1) of the prior probability mass function ($\rightarrow$ Definition I/1.4.1):

$$\lambda_{\mathrm{maxent}} = \arg\max_{\lambda} \mathrm{H}\left[p(\theta|\lambda, m)\right] \; ; \tag{1}$$

2) when θ is a continuous random variable ($\to$ Definition I/1.1.7), it maximizes the differential entropy ($\to$ Definition I/2.2.1) of the prior probability density function ($\to$ Definition I/1.4.4):

$$\lambda_{\mathrm{maxent}} = \arg\max_{\lambda} \mathrm{h}\left[p(\theta|\lambda, m)\right] \; . \tag{2}$$

Sources:
- Wikipedia (2020): "Prior probability"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-12-02; URL: https://en.wikipedia.org/wiki/Prior_probability#Uninformative_priors.

Metadata: ID: D121 | shortcut: prior-maxent | author: JoramSoch | date: 2020-12-02, 18:13.

5.2.7   Empirical Bayes priors

Definition: Let m be a generative model ($\to$ Definition I/5.1.1) with likelihood function ($\to$ Definition I/5.1.2) $p(y|\theta, m)$ and prior distribution ($\to$ Definition I/5.1.3) $p(\theta|\lambda, m)$ using prior hyperparameters ($\to$ Definition I/5.1.3) λ. Let $p(y|\lambda, m)$ be the marginal likelihood ($\to$ Definition I/5.1.9) when integrating the parameters out of the joint likelihood ($\to$ Proof I/5.1.10). Then, the prior distribution is called an "Empirical Bayes ($\to$ Definition I/5.3.3) prior", if it maximizes the logarithmized marginal likelihood:

$$\lambda_{\mathrm{EB}} = \arg\max_{\lambda} \log p(y|\lambda, m) \; . \tag{1}$$

Sources:
- Wikipedia (2020): "Empirical Bayes method"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-12-02; URL: https://en.wikipedia.org/wiki/Empirical_Bayes_method#Introduction.

Metadata: ID: D122 | shortcut: prior-eb | author: JoramSoch | date: 2020-12-02, 18:19.

5.2.8   Reference priors

Definition: Let m be a generative model ($\to$ Definition I/5.1.1) with likelihood function ($\to$ Definition I/5.1.2) $p(y|\theta, m)$ and prior distribution ($\to$ Definition I/5.1.3) $p(\theta|\lambda, m)$ using prior hyperparameters ($\to$ Definition I/5.1.3) λ. Let $p(\theta|y, \lambda, m)$ be the posterior distribution ($\to$ Definition I/5.1.7) that is proportional to the the joint likelihood ($\to$ Proof I/5.1.8). Then, the prior distribution is called a "reference prior", if it maximizes the expected ($\to$ Definition I/1.5.1) Kullback-Leibler divergence ($\to$ Definition I/2.5.1) of the posterior distribution relative to the prior distribution:

$$\lambda_{\mathrm{ref}} = \arg\max_{\lambda} \langle \mathrm{KL}\left[p(\theta|y, \lambda, m) \,||\, p(\theta|\lambda, m)\right] \rangle \; . \tag{1}$$

Sources:

5.3 Bayesian inference

5.3.1 Bayes' theorem

Theorem: Let A and B be two arbitrary statements about random variables ($\rightarrow$ Definition I/1.1.3), such as statements about the presence or absence of an event or about the value of a scalar, vector or matrix. Then, the conditional probability that A is true, given that B is true, is equal to

$$p(A|B) = \frac{p(B|A)\,p(A)}{p(B)} \;. \tag{1}$$

Proof: The conditional probability ($\rightarrow$ Definition I/1.2.4) is defined as the ratio of joint probability ($\rightarrow$ Definition I/1.2.2), i.e. the probability of both statements being true, and marginal probability ($\rightarrow$ Definition I/1.2.3), i.e. the probability of only the second one being true:

$$p(A|B) = \frac{p(A, B)}{p(B)} \;. \tag{2}$$

It can also be written down for the reverse situation, i.e. to calculate the probability that B is true, given that A is true:

$$p(B|A) = \frac{p(A, B)}{p(A)} \;. \tag{3}$$

Both equations can be rearranged for the joint probability

$$p(A|B)\,p(B) \overset{(2)}{=} p(A, B) \overset{(3)}{=} p(B|A)\,p(A) \tag{4}$$

from which Bayes' theorem can be directly derived:

$$p(A|B) \overset{(4)}{=} \frac{p(B|A)\,p(A)}{p(B)} \;. \tag{5}$$

- Koch, Karl-Rudolf (2007): "Rules of Probability"; in: *Introduction to Bayesian Statistics*, Springer, Berlin/Heidelberg, 2007, pp. 6/13, eqs. 2.12/2.38; URL: https://www.springer.com/de/book/9783540727231; DOI: 10.1007/978-3-540-72726-2.

Metadata: ID: P4 | shortcut: bayes-th | author: JoramSoch | date: 2019-09-27, 16:24.

5.3.2 Bayes' rule

Theorem: Let A_1, A_2 and B be arbitrary statements about random variables ($\rightarrow$ Definition I/1.1.3) where A_1 and A_2 are mutually exclusive. Then, Bayes' rule states that the posterior odds ($\rightarrow$ Definition "post-odd") are equal to the Bayes factor ($\rightarrow$ Definition IV/3.4.1) times the prior odds ($\rightarrow$ Definition "prior-odd"), i.e.

$$\frac{p(A_1|B)}{p(A_2|B)} = \frac{p(B|A_1)}{p(B|A_2)} \cdot \frac{p(A_1)}{p(A_2)} \ . \tag{1}$$

Proof: Using Bayes' theorem ($\rightarrow$ Proof I/5.3.1), the conditional probabilities ($\rightarrow$ Definition I/1.2.4) on the left are given by

$$p(A_1|B) = \frac{p(B|A_1) \cdot p(A_1)}{p(B)} \tag{2}$$

$$p(A_2|B) = \frac{p(B|A_2) \cdot p(A_2)}{p(B)} \ . \tag{3}$$

Dividing the two conditional probabilities by each other

$$\begin{aligned} \frac{p(A_1|B)}{p(A_2|B)} &= \frac{p(B|A_1) \cdot p(A_1)/p(B)}{p(B|A_2) \cdot p(A_2)/p(B)} \\ &= \frac{p(B|A_1)}{p(B|A_2)} \cdot \frac{p(A_1)}{p(A_2)} \ , \end{aligned} \tag{4}$$

one obtains the posterior odds ratio as given by the theorem.

5.3.3 Empirical Bayes

Definition: Let m be a generative model ($\rightarrow$ Definition I/5.1.1) with model parameters θ and hyper-parameters λ implying the likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, \lambda, m)$ and prior distribution ($\rightarrow$ Definition I/5.1.3) $p(\theta|\lambda, m)$. Then, an Empirical Bayes treatment of m, also referred to as "type II maximum likelihood ($\rightarrow$ Definition I/4.1.3)" or "evidence ($\rightarrow$ Definition IV/3.1.1) approximation", consists in

1) evaluating the marginal likelihood ($\rightarrow$ Definition I/5.1.9) of the model m

$$p(y|\lambda, m) = \int p(y|\theta, \lambda, m) \, (\theta|\lambda, m) \, \mathrm{d}\theta \ , \tag{1}$$

2) maximizing the log model evidence ($\rightarrow$ Definition IV/3.1.1) with respect to λ

$$\hat{\lambda} = \arg\max_{\lambda} \log p(y|\lambda, m) \tag{2}$$

3) and using the prior distribution ($\rightarrow$ Definition I/5.1.3) at this maximum

$$p(\theta|m) = p(\theta|\hat{\lambda}, m) \tag{3}$$

for Bayesian inference ($\rightarrow$ Proof I/5.3.1), i.e. obtaining the posterior distribution ($\rightarrow$ Proof I/5.1.8) and computing the marginal likelihood ($\rightarrow$ Proof I/5.1.10).

5.3.4   Variational Bayes

Definition: Let m be a generative model ($\rightarrow$ Definition I/5.1.1) with model parameters θ implying the likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, m)$ and prior distribution ($\rightarrow$ Definition I/5.1.3) $p(\theta|m)$. Then, a Variational Bayes treatment of m, also referred to as "approximate inference" or "variational inference", consists in

1) constructing an approximate posterior distribution ($\rightarrow$ Definition I/5.1.7)

$$q(\theta) \approx p(\theta|y, m) \, , \tag{1}$$

2) evaluating the variational free energy ($\rightarrow$ Definition IV/3.1.7)

$$F_q(m) = \int q(\theta) \log p(y|\theta, m) \, \mathrm{d}\theta - \int q(\theta) \frac{q(\theta)}{p(\theta|m)} \, \mathrm{d}\theta \tag{2}$$

3) and maximizing this function with respect to $q(\theta)$

$$\hat{q}(\theta) = \arg\max_q F_q(m) \, . \tag{3}$$

for Bayesian inference, i.e. obtaining the posterior distribution (from eq. (3)) and approximating the marginal likelihood (by plugging eq. (3) into eq. (2)).

Chapter II

Probability Distributions

1 Univariate discrete distributions

1.1 Discrete uniform distribution

1.1.1 Definition

Definition: Let X be a discrete random variable ($\rightarrow$ Definition I/1.1.3). Then, X is said to be uniformly distributed with minimum a and maximum b

$$X \sim \mathcal{U}(a, b) \,, \tag{1}$$

if and only if each integer between and including a and b occurs with the same probability.

Sources:
- Wikipedia (2020): "Discrete uniform distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-07-28; URL: https://en.wikipedia.org/wiki/Discrete_uniform_distribution.

Metadata: ID: D88 | shortcut: duni | author: JoramSoch | date: 2020-07-28, 04:05.

1.1.2 Probability mass function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a discrete uniform distribution ($\rightarrow$ Definition II/1.1.1):

$$X \sim \mathcal{U}(a, b) \,. \tag{1}$$

Then, the probability mass function ($\rightarrow$ Definition I/1.4.1) of X is

$$f_X(x) = \frac{1}{b - a + 1} \quad \text{where} \quad x \in \{a, a+1, \ldots, b-1, b\} \,. \tag{2}$$

Proof: A discrete uniform variable is defined as ($\rightarrow$ Definition II/1.1.1) having the same probability for each integer between and including a and b. The number of integers between and including a and b is

$$n = b - a + 1 \tag{3}$$

and because the sum across all probabilities ($\rightarrow$ Definition I/1.4.1) is

$$\sum_{x=a}^{b} f_X(x) = 1 \,, \tag{4}$$

we have

$$f_X(x) = \frac{1}{n} = \frac{1}{b - a + 1} \,. \tag{5}$$

- original work

Metadata: ID: P140 | shortcut: duni-pmf | author: JoramSoch | date: 2020-07-28, 04:57.

1.1.3 Cumulative distribution function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a discrete uniform distribution ($\rightarrow$ Definition II/1.1.1):

$$X \sim \mathcal{U}(a, b) \ . \tag{1}$$

Then, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of X is

$$F_X(x) = \begin{cases} 0 \ , & \text{if } x < a \\ \frac{\lfloor x \rfloor - a + 1}{b - a + 1} \ , & \text{if } a \leq x \leq b \\ 1 \ , & \text{if } x > b \ . \end{cases} \tag{2}$$

Proof: The probability mass function of the discrete uniform distribution ($\rightarrow$ Proof II/1.1.2) is

$$\mathcal{U}(x; a, b) = \frac{1}{b - a + 1} \quad \text{where} \quad x \in \{a, a+1, \ldots, b-1, b\} \ . \tag{3}$$

Thus, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) is:

$$F_X(x) = \int_{-\infty}^{x} \mathcal{U}(z; a, b) \, \mathrm{d}z \tag{4}$$

From (3), it follows that the cumulative probability increases step-wise by $1/n$ at each integer between and including a and b where

$$n = b - a + 1 \tag{5}$$

is the number of integers between and including a and b. This can be expressed by noting that

$$F_X(x) \overset{(3)}{=} \frac{\lfloor x \rfloor - a + 1}{n}, \text{ if } a \leq x \leq b \ . \tag{6}$$

Also, because $\Pr(X < a) = 0$, we have

$$F_X(x) \overset{(4)}{=} \int_{-\infty}^{x} 0 \, \mathrm{d}z = 0, \text{ if } x < a \tag{7}$$

and because $\Pr(X > b) = 0$, we have

$$\begin{aligned} F_X(x) &\overset{(4)}{=} \int_{-\infty}^{x} \mathcal{U}(z; a, b) \, \mathrm{d}z \\ &= \int_{-\infty}^{b} \mathcal{U}(z; a, b) \, \mathrm{d}z + \int_{b}^{x} \mathcal{U}(z; a, b) \, \mathrm{d}z \\ &= F_X(b) + \int_{b}^{x} 0 \, \mathrm{d}z \overset{(6)}{=} 1 + 0 \\ &= 1, \text{ if } x > b \ . \end{aligned} \tag{8}$$

This completes the proof.

1.1.4   Quantile function

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a discrete uniform distribution ($\to$ Definition II/1.1.1):

$$X \sim \mathcal{U}(a, b) \ . \tag{1}$$

Then, the quantile function ($\to$ Definition I/1.4.17) of X is

$$Q_X(p) = \begin{cases} -\infty \ , & \text{if } p = 0 \\ a(1-p) + (b+1)p - 1 \ , & \text{when } p \in \left\{ \frac{1}{n}, \frac{2}{n}, \ldots, \frac{b-a}{n}, 1 \right\} \ . \end{cases} \tag{2}$$

with $n = b - a + 1$.

Proof: The cumulative distribution function of the discrete uniform distribution ($\to$ Proof II/1.1.3) is:

$$F_X(x) = \begin{cases} 0 \ , & \text{if } x < a \\ \frac{\lfloor x \rfloor - a + 1}{b - a + 1} \ , & \text{if } a \leq x \leq b \\ 1 \ , & \text{if } x > b \ . \end{cases} \tag{3}$$

The quantile function $Q_X(p)$ is defined as ($\to$ Definition I/1.4.17) the smallest x, such that $F_X(x) = p$:

$$Q_X(p) = \min \left\{ x \in \mathbb{R} \mid F_X(x) = p \right\} \ . \tag{4}$$

Because the CDF only returns ($\to$ Proof II/1.1.3) multiples of $1/n$ with $n = b - a + 1$, the quantile function ($\to$ Definition I/1.4.17) is only defined for such values. First, we have $Q_X(p) = -\infty$, if $p = 0$. Second, since the cumulative probability increases step-wise ($\to$ Proof II/1.1.3) by $1/n$ at each integer between and including a and b, the minimum x at which

$$F_X(x) = \frac{c}{n} \quad \text{where} \quad c \in \{1, \ldots, n\} \tag{5}$$

is given by

$$Q_X\left(\frac{c}{n}\right) = a + \frac{c}{n} \cdot n - 1 \ . \tag{6}$$

Substituting $p = c/n$ and $n = b - a + 1$, we can finally show:

$$\begin{aligned} Q_X(p) &= a + p \cdot (b - a + 1) - 1 \\ &= a + pb - pa + p - 1 \\ &= a(1-p) + (b+1)p - 1 \ . \end{aligned} \tag{7}$$

1.2 Bernoulli distribution

1.2.1 Definition

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3). Then, X is said to follow a Bernoulli distribution with success probability p

$$X \sim \mathrm{Bern}(p) \,, \tag{1}$$

if $X = 1$ with probability ($\rightarrow$ Definition I/1.2.1) p and $X = 0$ with probability ($\rightarrow$ Definition I/1.2.1) $q = 1 - p$.

Sources:
- Wikipedia (2020): "Bernoulli distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-22; URL: https://en.wikipedia.org/wiki/Bernoulli_distribution.

Metadata: ID: D44 | shortcut: bern | author: JoramSoch | date: 2020-03-22, 17:40.

1.2.2 Probability mass function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a Bernoulli distribution ($\rightarrow$ Definition II/1.2.1):

$$X \sim \mathrm{Bern}(p) \,. \tag{1}$$

Then, the probability mass function ($\rightarrow$ Definition I/1.4.1) of X is

$$f_X(x) = \begin{cases} p \,, & \text{if } x = 1 \\ 1 - p \,, & \text{if } x = 0 \,. \end{cases} \tag{2}$$

Proof: This follows directly from the definition of the Bernoulli distribution ($\rightarrow$ Definition II/1.2.1).

Sources:
- original work

Metadata: ID: P96 | shortcut: bern-pmf | author: JoramSoch | date: 2020-05-11, 22:10.

1.2.3 Mean

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a Bernoulli distribution ($\rightarrow$ Definition II/1.2.1):

$$X \sim \mathrm{Bern}(p) \,. \tag{1}$$

Then, the mean or expected value ($\to$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = p \ . \tag{2}$$

Proof: The expected value ($\to$ Definition I/1.5.1) is the probability-weighted average of all possible values:

$$\mathrm{E}(X) = \sum_{x \in \mathcal{X}} x \cdot \mathrm{Pr}(X = x) \ . \tag{3}$$

Since there are only two possible outcomes for a Bernoulli random variable ($\to$ Proof II/1.2.2), we have:

$$
\begin{aligned}
\mathrm{E}(X) &= 0 \cdot \mathrm{Pr}(X = 0) + 1 \cdot \mathrm{Pr}(X = 1) \\
&= 0 \cdot (1 - p) + 1 \cdot p \\
&= p \ .
\end{aligned}
\tag{4}
$$

Sources:
- Wikipedia (2020): "Bernoulli distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-01-16; URL: https://en.wikipedia.org/wiki/Bernoulli_distribution#Mean.

Metadata: ID: P22 | shortcut: bern-mean | author: JoramSoch | date: 2020-01-16, 10:58.

1.3   Binomial distribution

1.3.1   Definition

Definition: Let X be a random variable ($\to$ Definition I/1.1.3). Then, X is said to follow a binomial distribution with number of trials n and success probability p

$$X \sim \mathrm{Bin}(n, p) \ , \tag{1}$$

if X is the number of successes observed in n independent ($\to$ Definition I/1.2.6) trials, where each trial has two possible outcomes ($\to$ Definition II/1.2.1) (success/failure) and the probability of success and failure are identical across trials ($p/q = 1 - p$).

Sources:
- Wikipedia (2020): "Binomial distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-22; URL: https://en.wikipedia.org/wiki/Binomial_distribution.

Metadata: ID: D45 | shortcut: bin | author: JoramSoch | date: 2020-03-22, 17:52.

1.3.2   Probability mass function

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a binomial distribution ($\to$ Definition II/1.3.1):

$$X \sim \mathrm{Bin}(n, p) \ . \tag{1}$$

Then, the probability mass function ($\rightarrow$ Definition I/1.4.1) of X is

$$f_X(x) = \binom{n}{x} p^x (1-p)^{n-x} . \tag{2}$$

Proof: A binomial variable is defined as ($\rightarrow$ Definition II/1.3.1) the number of successes observed in n independent ($\rightarrow$ Definition I/1.2.6) trials, where each trial has two possible outcomes ($\rightarrow$ Definition II/1.2.1) (success/failure) and the probability ($\rightarrow$ Definition I/1.2.1) of success and failure are identical across trials ($p/q = 1-p$).

If one has obtained x successes in n trials, one has also obtained $(n-x)$ failures. The probability of a particular series of x successes and $(n-x)$ failures, when order does matter, is

$$p^x (1-p)^{n-x} . \tag{3}$$

When order does not matter, there is a number of series consisting of x successes and $(n-x)$ failures. This number is equal to the number of possibilities in which x objects can be choosen from n objects which is given by the binomial coefficient:

$$\binom{n}{x} . \tag{4}$$

In order to obtain the probability of x successes and $(n-x)$ failures, when order does not matter, the probability in (3) has to be multiplied with the number of possibilities in (4) which gives

$$p(X = x | n, p) = \binom{n}{x} p^x (1-p)^{n-x} \tag{5}$$

which is equivalent to the expression above.

Sources:
- original work

Metadata: ID: P97 | shortcut: bin-pmf | author: JoramSoch | date: 2020-05-11, 22:35.

1.3.3 Mean

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a binomial distribution ($\rightarrow$ Definition II/1.3.1):

$$X \sim \mathrm{Bin}(n, p) . \tag{1}$$

Then, the mean or expected value ($\rightarrow$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = np . \tag{2}$$

Proof: By definition, a binomial random variable ($\rightarrow$ Definition II/1.3.1) is the sum of n independent and identical Bernoulli trials ($\rightarrow$ Definition II/1.2.1) with success probability p. Therefore, the expected value is

$$\mathrm{E}(X) = \mathrm{E}(X_1 + \ldots + X_n) \tag{3}$$

and because the expected value is a linear operator ($\rightarrow$ Proof I/1.5.5), this is equal to

$$
\begin{aligned}
\mathrm{E}(X) &= \mathrm{E}(X_1) + \ldots + \mathrm{E}(X_n) \\
&= \sum_{i=1}^{n} \mathrm{E}(X_i) \; .
\end{aligned}
\tag{4}
$$

With the expected value of the Bernoulli distribution ($\rightarrow$ Proof II/1.2.3), we have:

$$
\mathrm{E}(X) = \sum_{i=1}^{n} p = np \; .
\tag{5}
$$

Sources:
- Wikipedia (2020): "Binomial distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-01-16; URL: https://en.wikipedia.org/wiki/Binomial_distribution#Expected_value_and_variance.

Metadata: ID: P23 | shortcut: bin-mean | author: JoramSoch | date: 2020-01-16, 11:06.

1.4 Poisson distribution

1.4.1 Definition

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3). Then, X is said to follow a Poisson distribution with rate λ

$$
X \sim \mathrm{Poiss}(\lambda) \; ,
\tag{1}
$$

if and only if its probability mass function ($\rightarrow$ Definition I/1.4.1) is given by

$$
\mathrm{Poiss}(x; \lambda) = \frac{\lambda^x \, e^{-\lambda}}{x!}
\tag{2}
$$

where $x \in \mathbb{N}_0$ and $\lambda > 0$.

Sources:
- Wikipedia (2020): "Poisson distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-25; URL: https://en.wikipedia.org/wiki/Poisson_distribution#Definitions.

Metadata: ID: D62 | shortcut: poiss | author: JoramSoch | date: 2020-05-25, 23:34.

1.4.2 Probability mass function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a Poisson distribution ($\rightarrow$ Definition II/1.4.1):

$$
X \sim \mathrm{Poiss}(\lambda) \; .
\tag{1}
$$

Then, the probability mass function ($\rightarrow$ Definition I/1.4.1) of X is

$$f_X(x) = \frac{\lambda^x\, e^{-\lambda}}{x!}, \ x \in \mathbb{N}_0 \ . \tag{2}$$

Proof: This follows directly from the definition of the Poisson distribution ($\rightarrow$ Definition II/1.4.1).

Sources:
- original work

Metadata: ID: P102 | shortcut: poiss-pmf | author: JoramSoch | date: 2020-05-14, 20:39.

1.4.3 Mean

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a Poisson distribution ($\rightarrow$ Definition II/1.4.1):

$$X \sim \mathrm{Poiss}(\lambda) \ . \tag{1}$$

Then, the mean or expected value ($\rightarrow$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = \lambda \ . \tag{2}$$

Proof: The expected value of a discrete random variable ($\rightarrow$ Definition I/1.5.1) is defined as

$$\mathrm{E}(X) = \sum_{x \in \mathcal{X}} x \cdot f_X(x) \ , \tag{3}$$

such that, with the probability mass function of the Poisson distribution ($\rightarrow$ Proof II/1.4.2), we have:

$$
\begin{aligned}
\mathrm{E}(X) &= \sum_{x=0}^{\infty} x \cdot \frac{\lambda^x\, e^{-\lambda}}{x!} \\
&= \sum_{x=1}^{\infty} x \cdot \frac{\lambda^x\, e^{-\lambda}}{x!} \\
&= e^{-\lambda} \cdot \sum_{x=1}^{\infty} \frac{x}{x!} \lambda^x \\
&= \lambda e^{-\lambda} \cdot \sum_{x=1}^{\infty} \frac{\lambda^{x-1}}{(x-1)!} \ .
\end{aligned}
\tag{4}
$$

Substituting $z = x - 1$, such that $x = z + 1$, we get:

$$\mathrm{E}(X) = \lambda e^{-\lambda} \cdot \sum_{z=0}^{\infty} \frac{\lambda^z}{z!} \ . \tag{5}$$

Using the power series expansion of the exponential function

$$e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!} \ , \tag{6}$$

the expected value of X finally becomes

$$\begin{aligned} \mathrm{E}(X) &= \lambda e^{-\lambda} \cdot e^{\lambda} \\ &= \lambda \, . \end{aligned} \tag{7}$$

Sources:
- ProofWiki (2020): "Expectation of Poisson Distribution"; in: *ProofWiki*, retrieved on 2020-08-19; URL: https://proofwiki.org/wiki/Expectation_of_Poisson_Distribution.

Metadata: ID: P151 | shortcut: poiss-mean | author: JoramSoch | date: 2020-08-19, 06:09.

1.4.4   Variance

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a Poisson distribution ($\rightarrow$ Definition II/1.4.1):

$$X \sim \mathrm{Poiss}(\lambda) \, . \tag{1}$$

Then, the variance ($\rightarrow$ Definition I/1.6.1) of X is

$$\mathrm{Var}(X) = \lambda \, . \tag{2}$$

Proof: The variance ($\rightarrow$ Definition I/1.6.1) can be expressed in terms of expected values ($\rightarrow$ Proof I/1.6.3) as

$$\mathrm{Var}(X) = \mathrm{E}(X^2) - \mathrm{E}(X)^2 \, . \tag{3}$$

The expected value of a Poisson random variable ($\rightarrow$ Proof II/1.4.3) is

$$\mathrm{E}(X) = \lambda \, . \tag{4}$$

Let us now consider the expectation ($\rightarrow$ Definition I/1.5.1) of $X\,(X-1)$ which is defined as

$$\mathrm{E}[X\,(X-1)] = \sum_{x \in \mathcal{X}} x\,(x-1) \cdot f_X(x) \, , \tag{5}$$

such that, with the probability mass function of the Poisson distribution ($\rightarrow$ Proof II/1.4.2), we have:

$$\begin{aligned} \mathrm{E}[X\,(X-1)] &= \sum_{x=0}^{\infty} x\,(x-1) \cdot \frac{\lambda^x \, e^{-\lambda}}{x!} \\ &= \sum_{x=2}^{\infty} x\,(x-1) \cdot \frac{\lambda^x \, e^{-\lambda}}{x!} \\ &= e^{-\lambda} \cdot \sum_{x=2}^{\infty} x\,(x-1) \cdot \frac{\lambda^x}{x \cdot (x-1) \cdot (x-2)!} \\ &= \lambda^2 \cdot e^{-\lambda} \cdot \sum_{x=2}^{\infty} \frac{\lambda^{x-2}}{(x-2)!} \, . \end{aligned} \tag{6}$$

Substituting $z = x - 2$, such that $x = z + 2$, we get:

$$\mathrm{E}[X\,(X-1)] = \lambda^2 \cdot e^{-\lambda} \cdot \sum_{z=0}^{\infty} \frac{\lambda^z}{z!} \; . \tag{7}$$

Using the power series expansion of the exponential function

$$e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!} \; , \tag{8}$$

the expected value of $X\,(X-1)$ finally becomes

$$\mathrm{E}[X\,(X-1)] = \lambda^2 \cdot e^{-\lambda} \cdot e^{\lambda} = \lambda^2 \; . \tag{9}$$

Note that this expectation can be written as

$$\mathrm{E}[X\,(X-1)] = \mathrm{E}(X^2 - X) = \mathrm{E}(X^2) - \mathrm{E}(X) \; , \tag{10}$$

such that, with (9) and (4), we have:

$$\mathrm{E}(X^2) - \mathrm{E}(X) = \lambda^2 \quad \Rightarrow \quad \mathrm{E}(X^2) = \lambda^2 + \lambda \; . \tag{11}$$

Plugging (11) and (4) into (3), the variance of a Poisson random variable finally becomes

$$\mathrm{Var}(X) = \lambda^2 + \lambda - \lambda^2 = \lambda \; . \tag{12}$$

2   Multivariate discrete distributions

2.1   Categorical distribution

2.1.1   Definition

Definition: Let X be a random vector ($\rightarrow$ Definition I/1.1.4). Then, X is said to follow a categorical distribution with success probability $p_1, \ldots, p_k$

$$X \sim \mathrm{Cat}([p_1, \ldots, p_k]) \,, \tag{1}$$

if $X = e_i$ with probability ($\rightarrow$ Definition I/1.2.1) p_i for all $i = 1, \ldots, k$, where e_i is the i-th elementary row vector, i.e. a $1 \times k$ vector of zeros with a one in i-th position.

Sources:
- Wikipedia (2020): "Categorical distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-22; URL: https://en.wikipedia.org/wiki/Categorical_distribution.

Metadata: ID: D46 | shortcut: cat | author: JoramSoch | date: 2020-03-22, 18:09.

2.1.2   Probability mass function

Theorem: Let X be a random vector ($\rightarrow$ Definition I/1.1.4) following a categorical distribution ($\rightarrow$ Definition II/2.1.1):

$$X \sim \mathrm{Cat}([p_1, \ldots, p_k]) \,. \tag{1}$$

Then, the probability mass function ($\rightarrow$ Definition I/1.4.1) of X is

$$f_X(x) = \begin{cases} p_1 \,, & \text{if } x = e_1 \\ \vdots & \phantom{\text{if } x =}\vdots \\ p_k \,, & \text{if } x = e_k \,. \end{cases} \tag{2}$$

where $e_1, \ldots, e_k$ are the $1 \times k$ elementary row vectors.

Proof: This follows directly from the definition of the categorical distribution ($\rightarrow$ Definition II/2.1.1).

Sources:
- original work

Metadata: ID: P98 | shortcut: cat-pmf | author: JoramSoch | date: 2020-05-11, 22:58.

2.1.3   Mean

Theorem: Let X be a random vector ($\rightarrow$ Definition I/1.1.4) following a categorical distribution ($\rightarrow$ Definition II/2.1.1):

$$X \sim \mathrm{Cat}([p_1, \ldots, p_k]) \,. \tag{1}$$

Then, the mean or expected value ($\rightarrow$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = [p_1, \ldots, p_k] \ . \tag{2}$$

Proof: If we conceive the outcome of a categorical distribution ($\to$ Definition II/2.1.1) to be a $1 \times k$ vector, then the elementary row vectors $e_1 = [1, 0, \ldots, 0]$, ..., $e_k = [0, \ldots, 0, 1]$ are all the possible outcomes and they occur with probabilities $\Pr(X = e_1) = p_1$, ..., $\Pr(X = e_k) = p_k$. Consequently, the expected value ($\to$ Definition I/1.5.1) is

$$\begin{aligned}
\mathrm{E}(X) &= \sum_{x \in \mathcal{X}} x \cdot \Pr(X = x) \\
&= \sum_{i=1}^{k} e_i \cdot \Pr(X = e_i) \\
&= \sum_{i=1}^{k} e_i \cdot p_i \\
&= [p_1, \ldots, p_k] \ .
\end{aligned} \tag{3}$$

2.2 Multinomial distribution

2.2.1 Definition

Definition: Let X be a random vector ($\to$ Definition I/1.1.4). Then, X is said to follow a multinomial distribution with number of trials n and category probabilities $p_1, \ldots, p_k$

$$X \sim \mathrm{Mult}(n, [p_1, \ldots, p_k]) \ , \tag{1}$$

if X are the numbers of observations belonging to k distinct categories in n independent ($\to$ Definition I/1.2.6) trials, where each trial has k possible outcomes ($\to$ Definition II/2.1.1) and the category probabilities are identical across trials.

Sources:
- Wikipedia (2020): "Binomial distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-22; URL: https://en.wikipedia.org/wiki/Multinomial_distribution.

Metadata: ID: D47 | shortcut: mult | author: JoramSoch | date: 2020-03-22, 17:52.

2.2.2 Probability mass function

Theorem: Let X be a random vector ($\to$ Definition I/1.1.4) following a multinomial distribution ($\to$ Definition II/2.2.1):

$$X \sim \mathrm{Mult}(n, [p_1, \ldots, p_k]) \ . \tag{1}$$

Then, the probability mass function ($\rightarrow$ Definition I/1.4.1) of X is

$$f_X(x) = \binom{n}{x_1, \ldots, x_k} \prod_{i=1}^{k} p_i{}^{x_i} \ . \tag{2}$$

Proof: A multinomial variable is defined as ($\rightarrow$ Definition II/2.2.1) a vector of the numbers of observations belonging to k distinct categories in n independent ($\rightarrow$ Definition I/1.2.6) trials, where each trial has k possible outcomes ($\rightarrow$ Definition II/2.1.1) and the category probabilities ($\rightarrow$ Definition I/1.2.1) are identical across trials.

The probability of a particular series of x_1 observations for category 1, x_2 observations for category 2 etc., when order does matter, is

$$\prod_{i=1}^{k} p_i{}^{x_i} \ . \tag{3}$$

When order does not matter, there is a number of series consisting of x_1 observations for category 1, ..., x_k observations for category k. This number is equal to the number of possibilities in which x_1 category 1 objects, ..., x_k category k objects can be distributed in a sequence of n objects which is given by the multinomial coefficient that can be expressed in terms of factorials:

$$\binom{n}{x_1, \ldots, x_k} = \frac{n!}{x_1! \cdot \ldots \cdot x_k!} \ . \tag{4}$$

In order to obtain the probability of x_1 observations for category 1, ..., x_k observations for category k, when order does not matter, the probability in (3) has to be multiplied with the number of possibilities in (4) which gives

$$p(X = x | n, [p_1, \ldots, p_k]) = \binom{n}{x_1, \ldots, x_k} \prod_{i=1}^{k} p_i{}^{x_i} \tag{5}$$

which is equivalent to the expression above.

Sources:
- original work

Metadata: ID: P99 | shortcut: mult-pmf | author: JoramSoch | date: 2020-05-11, 23:30.

2.2.3 Mean

Theorem: Let X be a random vector ($\rightarrow$ Definition I/1.1.4) following a multinomial distribution ($\rightarrow$ Definition II/2.2.1):

$$X \sim \mathrm{Mult}(n, [p_1, \ldots, p_k]) \ . \tag{1}$$

Then, the mean or expected value ($\rightarrow$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = [np_1, \ldots, np_k] \ . \tag{2}$$

Proof: By definition, a multinomial random variable ($\rightarrow$ Definition II/2.2.1) is the sum of n independent and identical categorical trials ($\rightarrow$ Definition II/2.1.1) with category probabilities $p_1, \ldots, p_k$. Therefore, the expected value is

$$\mathrm{E}(X) = \mathrm{E}(X_1 + \ldots + X_n) \tag{3}$$

and because the expected value is a linear operator ($\rightarrow$ Proof I/1.5.5), this is equal to

$$\begin{aligned} \mathrm{E}(X) &= \mathrm{E}(X_1) + \ldots + \mathrm{E}(X_n) \\ &= \sum_{i=1}^{n} \mathrm{E}(X_i) \ . \end{aligned} \tag{4}$$

With the expected value of the categorical distribution ($\rightarrow$ Proof II/2.1.3), we have:

$$\mathrm{E}(X) = \sum_{i=1}^{n} [p_1, \ldots, p_k] = n \cdot [p_1, \ldots, p_k] = [np_1, \ldots, np_k] \ . \tag{5}$$

3   Univariate continuous distributions

3.1   Continuous uniform distribution

3.1.1   Definition

Definition: Let X be a continuous random variable ($\to$ Definition I/1.1.3). Then, X is said to be uniformly distributed with minimum a and maximum b

$$X \sim \mathcal{U}(a, b) \, , \tag{1}$$

if and only if each value between and including a and b occurs with the same probability.

Sources:
- Wikipedia (2020): "Uniform distribution (continuous)"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-01-27; URL: https://en.wikipedia.org/wiki/Uniform_distribution_(continuous).

Metadata: ID: D3 | shortcut: cuni | author: JoramSoch | date: 2020-01-27, 14:05.

3.1.2   Probability density function

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a continuous uniform distribution ($\to$ Definition II/3.1.1):

$$X \sim \mathcal{U}(a, b) \, . \tag{1}$$

Then, the probability density function ($\to$ Definition I/1.4.4) of X is

$$f_X(x) = \begin{cases} \frac{1}{b-a} \, , & \text{if } a \leq x \leq b \\[2mm] 0 \, , & \text{otherwise} \, . \end{cases} \tag{2}$$

Proof: A continuous uniform variable is defined as ($\to$ Definition II/3.1.1) having a constant probability density between minimum a and maximum b. Therefore,

$$\begin{aligned} f_X(x) &\propto 1 \quad \text{for all} \quad x \in [a, b] \quad \text{and} \\ f_X(x) &= 0, \quad \text{if} \quad x < a \quad \text{or} \quad x > b \, . \end{aligned} \tag{3}$$

To ensure that $f_X(x)$ is a proper probability density function ($\to$ Definition I/1.4.4), the integral over all non-zero probabilities has to sum to 1. Therefore,

$$f_X(x) = \frac{1}{c(a, b)} \quad \text{for all} \quad x \in [a, b] \tag{4}$$

where the normalization factor $c(a, b)$ is specified, such that

$$\frac{1}{c(a, b)} \int_a^b 1 \, \mathrm{d}x = 1 \, . \tag{5}$$

Solving this for $c(a, b)$, we obtain:

$$
\begin{aligned}
\int_a^b 1 \, \mathrm{d}x &= c(a, b) \\
[x]_a^b &= c(a, b) \\
c(a, b) &= b - a \ .
\end{aligned}
\tag{6}
$$

Sources:

- original work

Metadata: ID: P37 | shortcut: cuni-pdf | author: JoramSoch | date: 2020-01-31, 15:41.

3.1.3 Cumulative distribution function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a continuous uniform distribution ($\rightarrow$ Definition II/3.1.1):

$$
X \sim \mathcal{U}(a, b) \ .
\tag{1}
$$

Then, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of X is

$$
F_X(x) = \begin{cases} 0 \ , & \text{if } x < a \\ \frac{x-a}{b-a} \ , & \text{if } a \le x \le b \\ 1 \ , & \text{if } x > b \ . \end{cases}
\tag{2}
$$

Proof: The probability density function of the continuous uniform distribution ($\rightarrow$ Proof II/3.1.2) is:

$$
\mathcal{U}(x; a, b) = \begin{cases} \frac{1}{b-a} \ , & \text{if } a \le x \le b \\ 0 \ , & \text{otherwise} \ . \end{cases}
\tag{3}
$$

Thus, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) is:

$$
F_X(x) = \int_{-\infty}^x \mathcal{U}(z; a, b) \, \mathrm{d}z
\tag{4}
$$

First of all, if $x < a$, we have

$$
F_X(x) = \int_{-\infty}^x 0 \, \mathrm{d}z = 0 \ .
\tag{5}
$$

Moreover, if $a \le x \le b$, we have using (3)

$$F_X(x) = \int_{-\infty}^{a} \mathcal{U}(z; a, b)\,\mathrm{d}z + \int_{a}^{x} \mathcal{U}(z; a, b)\,\mathrm{d}z$$

$$= \int_{-\infty}^{a} 0\,\mathrm{d}z + \int_{a}^{x} \frac{1}{b-a}\,\mathrm{d}z \tag{6}$$

$$= 0 + \frac{1}{b-a}[z]_a^x$$

$$= \frac{x-a}{b-a} \ .$$

Finally, if $x > b$, we have

$$F_X(x) = \int_{-\infty}^{b} \mathcal{U}(z; a, b)\,\mathrm{d}z + \int_{b}^{x} \mathcal{U}(z; a, b)\,\mathrm{d}z$$

$$= F_X(b) + \int_{b}^{x} 0\,\mathrm{d}z \tag{7}$$

$$= \frac{b-a}{b-a} + 0$$

$$= 1 \ .$$

This completes the proof.

3.1.4   Quantile function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a continuous uniform distribution ($\rightarrow$ Definition II/3.1.1):

$$X \sim \mathcal{U}(a, b) \ . \tag{1}$$

Then, the quantile function ($\rightarrow$ Definition I/1.4.17) of X is

$$Q_X(p) = \begin{cases} -\infty \ , & \text{if } p = 0 \\ bp + a(1-p) \ , & \text{if } p > 0 \ . \end{cases} \tag{2}$$

Proof: The cumulative distribution function of the continuous uniform distribution ($\rightarrow$ Proof II/3.1.3) is:

$$F_X(x) = \begin{cases} 0 \ , & \text{if } x < a \\ \frac{x-a}{b-a} \ , & \text{if } a \leq x \leq b \\ 1 \ , & \text{if } x > b \ . \end{cases} \tag{3}$$

The quantile function $Q_X(p)$ is defined as ($\rightarrow$ Definition I/1.4.17) the smallest x, such that $F_X(x) = p$:

$$Q_X(p) = \min \{x \in \mathbb{R} \mid F_X(x) = p\} \ . \tag{4}$$

Thus, we have $Q_X(p) = -\infty$, if $p = 0$. When $p > 0$, it holds that ($\rightarrow$ Proof I/1.4.18)

$$Q_X(p) = F_X^{-1}(x) \ . \tag{5}$$

This can be derived by rearranging equation (3):

$$\begin{aligned} p &= \frac{x - a}{b - a} \\ x &= p(b - a) + a \\ x &= bp + a(1 - p) \ . \end{aligned} \tag{6}$$

Sources:
- original work

Metadata: ID: P39 | shortcut: cuni-qf | author: JoramSoch | date: 2020-01-02, 18:27.

3.1.5   Mean

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a continuous uniform distribution ($\rightarrow$ Definition II/3.1.1):

$$X \sim \mathcal{U}(a, b) \ . \tag{1}$$

Then, the mean or expected value ($\rightarrow$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = \frac{1}{2}(a + b) \ . \tag{2}$$

Proof: The expected value ($\rightarrow$ Definition I/1.5.1) is the probability-weighted average over all possible values:

$$\mathrm{E}(X) = \int_{\mathcal{X}} x \cdot f_X(x) \, \mathrm{d}x \ . \tag{3}$$

With the probability density function of the continuous uniform distribution ($\rightarrow$ Proof II/3.1.2), this becomes:

$$
\begin{aligned}
\mathrm{E}(X) &= \int_a^b x \cdot \frac{1}{b-a} \, \mathrm{d}x \\
&= \left[\frac{1}{2} \frac{x^2}{b-a} \right]_a^b \\
&= \frac{1}{2} \frac{b^2 - a^2}{b-a} \\
&= \frac{1}{2} \frac{(b+a)(b-a)}{b-a} \\
&= \frac{1}{2}(a+b) \ .
\end{aligned}
\tag{4}
$$

Sources:

* original work

Metadata: ID: P82 | shortcut: cuni-mean | author: JoramSoch | date: 2020-03-16, 16:12.

3.1.6 Median

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a continuous uniform distribution ($\rightarrow$ Definition II/3.1.1):

$$
X \sim \mathcal{U}(a, b) \ .
\tag{1}
$$

Then, the median ($\rightarrow$ Definition I/1.9.1) of X is

$$
\mathrm{median}(X) = \frac{1}{2}(a+b) \ .
\tag{2}
$$

Proof: The median ($\rightarrow$ Definition I/1.9.1) is the value at which the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) is $1/2$:

$$
F_X(\mathrm{median}(X)) = \frac{1}{2} \ .
\tag{3}
$$

The cumulative distribution function of the continuous uniform distribution ($\rightarrow$ Proof II/3.1.3) is

$$
F_X(x) = \begin{cases} 0 \ , & \text{if } x < a \\ \frac{x-a}{b-a} \ , & \text{if } a \le x \le b \\ 1 \ , & \text{if } x > b \ . \end{cases}
\tag{4}
$$

Thus, the inverse CDF ($\rightarrow$ Proof II/3.1.4) is

$$
x = bp + a(1 - p) \ .
\tag{5}
$$

Setting $p = 1/2$, we obtain:

$$
\mathrm{median}(X) = b \cdot \frac{1}{2} + a \cdot \left(1 - \frac{1}{2} \right) = \frac{1}{2}(a+b) \ .
\tag{6}
$$

3.1.7 Mode

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a continuous uniform distribution ($\to$ Definition II/3.1.1):

$$X \sim \mathcal{U}(a, b) \ . \tag{1}$$

Then, the mode ($\to$ Definition I/1.9.2) of X is

$$\mathrm{mode}(X) \in [a, b] \ . \tag{2}$$

Proof: The mode ($\to$ Definition I/1.9.2) is the value which maximizes the probability density function ($\to$ Definition I/1.4.4):

$$\mathrm{mode}(X) = \arg\max_x f_X(x) \ . \tag{3}$$

The probability density function of the continuous uniform distribution ($\to$ Proof II/3.1.2) is:

$$f_X(x) = \begin{cases} \frac{1}{b-a} \ , & \text{if } a \leq x \leq b \\ 0 \ , & \text{otherwise} \ . \end{cases} \tag{4}$$

Since the PDF attains its only non-zero value whenever $a \leq x \leq b$,

$$\max_x f_X(x) = \frac{1}{b - a} \ , \tag{5}$$

any value in the interval $[a, b]$ may be considered the mode of X.

3.2 Normal distribution

3.2.1 Definition

Definition: Let X be a random variable ($\to$ Definition I/1.1.3). Then, X is said to be normally distributed with mean μ and variance σ^2 (or, standard deviation σ)

$$X \sim \mathcal{N}(\mu, \sigma^2) \ , \tag{1}$$

if and only if its probability density function ($\to$ Definition I/1.4.4) is given by

$$\mathcal{N}(x; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \tag{2}$$

where $\mu \in \mathbb{R}$ and $\sigma^2 > 0$.

Sources:
- Wikipedia (2020): "Normal distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-01-27; URL: https://en.wikipedia.org/wiki/Normal_distribution.

Metadata: ID: D4 | shortcut: norm | author: JoramSoch | date: 2020-01-27, 14:15.

3.2.2   Standard normal distribution

Definition: Let X be a random variable ($\to$ Definition I/1.1.3). Then, X is said to be standard normally distributed, if X follows a normal distribution ($\to$ Definition II/3.2.1) with mean $\mu = 0$ and variance $\sigma^2 = 1$:

$$X \sim \mathcal{N}(0, 1) \, . \tag{1}$$

Sources:
- Wikipedia (2020): "Normal distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-26; URL: https://en.wikipedia.org/wiki/Normal_distribution#Standard_normal_distribution.

Metadata: ID: D63 | shortcut: snorm | author: JoramSoch | date: 2020-05-26, 23:32.

3.2.3   Relation to standard normal distribution

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a normal distribution ($\to$ Definition II/3.2.1) with mean μ and variance σ^2:

$$X \sim \mathcal{N}(\mu, \sigma^2) \, . \tag{1}$$

Then, the quantity $Z = (X - \mu)/\sigma$ will have a standard normal distribution ($\to$ Definition II/3.2.2) with mean 0 and variance 1:

$$Z = \frac{X - \mu}{\sigma} \sim \mathcal{N}(0, 1) \, . \tag{2}$$

Proof: Note that Z is a function of X

$$Z = g(X) = \frac{X - \mu}{\sigma} \tag{3}$$

with the inverse function

$$X = g^{-1}(Z) = \sigma Z + \mu \, . \tag{4}$$

Because σ is positive, $g(X)$ is strictly increasing and we can calculate the cumulative distribution function of a strictly increasing function ($\to$ Proof I/1.4.9) as

$$F_Y(y) = \begin{cases} 0 \,, & \text{if } y < \min(\mathcal{Y}) \\ F_X(g^{-1}(y)) \,, & \text{if } y \in \mathcal{Y} \\ 1 \,, & \text{if } y > \max(\mathcal{Y}) \,. \end{cases} \tag{5}$$

The cumulative distribution function of the normally distributed ($\rightarrow$ Proof II/3.2.9) X is

$$F_X(x) = \int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{t-\mu}{\sigma}\right)^2\right] \, dt \,. \tag{6}$$

Applying (5) to (6), we have:

$$\begin{aligned} F_Z(z) &\overset{(5)}{=} F_X(g^{-1}(z)) \\ &\overset{(6)}{=} \int_{-\infty}^{\sigma z + \mu} \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{t-\mu}{\sigma}\right)^2\right] \, dt \,. \end{aligned} \tag{7}$$

Substituting $s = (t - \mu)/\sigma$, such that $t = \sigma s + \mu$, we obtain

$$\begin{aligned} F_Z(z) &= \int_{(-\infty-\mu)/\sigma}^{([\sigma z + \mu]-\mu)/\sigma} \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{(\sigma s + \mu)-\mu}{\sigma}\right)^2\right] \, d(\sigma s + \mu) \\ &= \int_{-\infty}^{z} \frac{\sigma}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}s^2\right] \, ds \\ &= \int_{-\infty}^{z} \frac{1}{\sqrt{2\pi}} \cdot \exp\left[-\frac{1}{2}s^2\right] \, ds \end{aligned} \tag{8}$$

which is the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of the standard normal distribution ($\rightarrow$ Definition II/3.2.2).

3.2.4 Relation to standard normal distribution

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a normal distribution ($\rightarrow$ Definition II/3.2.1) with mean μ and variance σ^2:

$$X \sim \mathcal{N}(\mu, \sigma^2) \,. \tag{1}$$

Then, the quantity $Z = (X - \mu)/\sigma$ will have a standard normal distribution ($\rightarrow$ Definition II/3.2.2) with mean 0 and variance 1:

$$Z = \frac{X - \mu}{\sigma} \sim \mathcal{N}(0, 1) \,. \tag{2}$$

Proof: Note that Z is a function of X

$$Z = g(X) = \frac{X - \mu}{\sigma} \tag{3}$$

with the inverse function

$$X = g^{-1}(Z) = \sigma Z + \mu \; . \tag{4}$$

Because σ is positive, $g(X)$ is strictly increasing and we can calculate the probability density function of a strictly increasing function ($\rightarrow$ Proof I/1.4.5) as

$$f_Y(y) = \begin{cases} f_X(g^{-1}(y)) \frac{\mathrm{d}g^{-1}(y)}{\mathrm{d}y} \; , & \text{if } y \in \mathcal{Y} \\ 0 \; , & \text{if } y \notin \mathcal{Y} \end{cases} \tag{5}$$

where $\mathcal{Y} = \{y = g(x) : x \in \mathcal{X}\}$. With the probability density function of the normal distribution ($\rightarrow$ Proof II/3.2.7), we have

$$\begin{aligned} f_Z(z) &= \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{g^{-1}(z) - \mu}{\sigma}\right)^2\right] \cdot \frac{\mathrm{d}g^{-1}(z)}{\mathrm{d}z} \\ &= \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{(\sigma z + \mu) - \mu}{\sigma}\right)^2\right] \cdot \frac{\mathrm{d}(\sigma z + \mu)}{\mathrm{d}z} \\ &= \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}z^2\right] \cdot \sigma \\ &= \frac{1}{\sqrt{2\pi}} \cdot \exp\left[-\frac{1}{2}z^2\right] \end{aligned} \tag{6}$$

which is the probability density function ($\rightarrow$ Definition I/1.4.4) of the standard normal distribution ($\rightarrow$ Definition II/3.2.2).

3.2.5   Relation to standard normal distribution

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a normal distribution ($\rightarrow$ Definition II/3.2.1) with mean μ and variance σ^2:

$$X \sim \mathcal{N}(\mu, \sigma^2) \; . \tag{1}$$

Then, the quantity $Z = (X - \mu)/\sigma$ will have a standard normal distribution ($\rightarrow$ Definition II/3.2.2) with mean 0 and variance 1:

$$Z = \frac{X - \mu}{\sigma} \sim \mathcal{N}(0, 1) \; . \tag{2}$$

Proof: The linear transformation theorem for multivariate normal distribution ($\rightarrow$ Proof II/4.1.5) states

$$x \sim \mathcal{N}(\mu, \Sigma) \quad \Rightarrow \quad y = Ax + b \sim \mathcal{N}(A\mu + b, A\Sigma A^{\mathrm{T}}) \tag{3}$$

where x is an $n \times 1$ random vector ($\rightarrow$ Definition I/1.1.4) following a multivariate normal distribution ($\rightarrow$ Definition II/4.1.1) with mean μ and covariance Σ, A is an $m \times n$ matrix and b is an $m \times 1$ vector. Note that

$$Z = \frac{X - \mu}{\sigma} = \frac{X}{\sigma} - \frac{\mu}{\sigma} \tag{4}$$

is a special case of (3) with $x = X$, $\mu = \mu$, $\Sigma = \sigma^2$, $A = 1/\sigma$ and $b = \mu/\sigma$. Applying theorem (3) to Z as a function of X, we have

$$X \sim \mathcal{N}(\mu, \sigma^2) \quad \Rightarrow \quad Z = \frac{X}{\sigma} - \frac{\mu}{\sigma} \sim \mathcal{N}\left(\frac{\mu}{\sigma} - \frac{\mu}{\sigma}, \frac{1}{\sigma} \cdot \sigma^2 \cdot \frac{1}{\sigma}\right) \tag{5}$$

which results in the distribution:

$$Z \sim \mathcal{N}(0, 1) . \tag{6}$$

3.2.6 Gaussian integral

Theorem: The definite integral of $\exp\left[-x^2\right]$ from $-\infty$ to $+\infty$ is equal to the square root of π:

$$\int_{-\infty}^{+\infty} \exp\left[-x^2\right] \, \mathrm{d}x = \sqrt{\pi} . \tag{1}$$

Proof: Let

$$I = \int_0^\infty \exp\left[-x^2\right] \, \mathrm{d}x \tag{2}$$

and

$$I_P = \int_0^P \exp\left[-x^2\right] \, \mathrm{d}x = \int_0^P \exp\left[-y^2\right] \, \mathrm{d}y . \tag{3}$$

Then, we have

$$\lim_{P \to \infty} I_P = I \tag{4}$$

and

$$\lim_{P \to \infty} I_P^2 = I^2 . \tag{5}$$

Moreover, we can write

$$I_P^2 \overset{(3)}{=} \left(\int_0^P \exp\left[-x^2\right] \, \mathrm{d}x \right) \left(\int_0^P \exp\left[-y^2\right] \, \mathrm{d}y \right)$$

$$= \int_0^P \int_0^P \exp\left[-\left(x^2 + y^2\right)\right] \, \mathrm{d}x \, \mathrm{d}y \tag{6}$$

$$= \iint_{S_P} \exp\left[-\left(x^2 + y^2\right)\right] \, \mathrm{d}x \, \mathrm{d}y$$

where S_P is the square with corners $(0,0)$, $(0,P)$, (P,P) and $(P,0)$. For this integral, we can write down the following inequality

$$\iint_{C_1} \exp\left[-\left(x^2 + y^2\right)\right] \, \mathrm{d}x \, \mathrm{d}y \leq I_P^2 \leq \iint_{C_2} \exp\left[-\left(x^2 + y^2\right)\right] \, \mathrm{d}x \, \mathrm{d}y \tag{7}$$

where C_1 and C_2 are the regions in the first quadrant bounded by circles with center at $(0,0)$ and going through the points $(0,P)$ and (P,P), respectively. The radii of these two circles are $r_1 = \sqrt{P^2} = P$ and $r_2 = \sqrt{2P^2} = P\sqrt{2}$, such that we can rewrite equation (7) using polar coordinates as

$$\int_0^{\frac{\pi}{2}} \int_0^{r_1} \exp\left[-r^2\right] r \, \mathrm{d}r \, \mathrm{d}\theta \leq I_P^2 \leq \int_0^{\frac{\pi}{2}} \int_0^{r_2} \exp\left[-r^2\right] r \, \mathrm{d}r \, \mathrm{d}\theta \ . \tag{8}$$

Solving the definite integrals yields:

$$\int_0^{\frac{\pi}{2}} \int_0^{r_1} \exp\left[-r^2\right] r \, \mathrm{d}r \, \mathrm{d}\theta \leq I_P^2 \leq \int_0^{\frac{\pi}{2}} \int_0^{r_2} \exp\left[-r^2\right] r \, \mathrm{d}r \, \mathrm{d}\theta$$

$$\int_0^{\frac{\pi}{2}} \left[-\frac{1}{2}\exp\left[-r^2\right]\right]_0^{r_1} \mathrm{d}\theta \leq I_P^2 \leq \int_0^{\frac{\pi}{2}} \left[-\frac{1}{2}\exp\left[-r^2\right]\right]_0^{r_2} \mathrm{d}\theta$$

$$-\frac{1}{2}\int_0^{\frac{\pi}{2}} \left(\exp\left[-r_1^2\right] - 1\right) \mathrm{d}\theta \leq I_P^2 \leq -\frac{1}{2}\int_0^{\frac{\pi}{2}} \left(\exp\left[-r_2^2\right] - 1\right) \mathrm{d}\theta \tag{9}$$

$$-\frac{1}{2}\left[\left(\exp\left[-r_1^2\right] - 1\right)\theta\right]_0^{\frac{\pi}{2}} \leq I_P^2 \leq -\frac{1}{2}\left[\left(\exp\left[-r_2^2\right] - 1\right)\theta\right]_0^{\frac{\pi}{2}}$$

$$\frac{1}{2}\left(1 - \exp\left[-r_1^2\right]\right)\frac{\pi}{2} \leq I_P^2 \leq \frac{1}{2}\left(1 - \exp\left[-r_2^2\right]\right)\frac{\pi}{2}$$

$$\frac{\pi}{4}\left(1 - \exp\left[-P^2\right]\right) \leq I_P^2 \leq \frac{\pi}{4}\left(1 - \exp\left[-2P^2\right]\right)$$

Calculating the limit for $P \to \infty$, we obtain

$$\lim_{P \to \infty} \frac{\pi}{4}\left(1 - \exp\left[-P^2\right]\right) \leq \lim_{P \to \infty} I_P^2 \leq \lim_{P \to \infty} \frac{\pi}{4}\left(1 - \exp\left[-2P^2\right]\right)$$

$$\frac{\pi}{4} \leq I^2 \leq \frac{\pi}{4} \ , \tag{10}$$

such that we have a preliminary result for I:

$$I^2 = \frac{\pi}{4} \quad \Rightarrow \quad I = \frac{\sqrt{\pi}}{2} \ . \tag{11}$$

Because the integrand in (1) is an even function, we can calculate the final result as follows:

$$\int_{-\infty}^{+\infty} \exp\left[-x^2\right] \mathrm{d}x = 2 \int_0^{\infty} \exp\left[-x^2\right] \mathrm{d}x$$
$$\overset{(11)}{=} 2 \frac{\sqrt{\pi}}{2}$$
$$= \sqrt{\pi} \; . \tag{12}$$

3.2.7 Probability density function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a normal distribution ($\rightarrow$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) \; . \tag{1}$$

Then, the probability density function ($\rightarrow$ Definition I/1.4.4) of X is

$$f_X(x) = \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \; . \tag{2}$$

Proof: This follows directly from the definition of the normal distribution ($\rightarrow$ Definition II/3.2.1).

3.2.8 Moment-generating function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a normal distribution ($\rightarrow$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) \; . \tag{1}$$

Then, the moment-generating function ($\rightarrow$ Definition I/1.4.19) of X is

$$M_X(t) = \exp\left[\mu t + \frac{1}{2}\sigma^2 t^2\right] \; . \tag{2}$$

Proof: The probability density function of the normal distribution ($\rightarrow$ Proof II/3.2.7) is

$$f_X(x) = \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \tag{3}$$

and the moment-generating function ($\rightarrow$ Definition I/1.4.19) is defined as

$$M_X(t) = \mathrm{E}\left[e^{tX}\right] \ . \tag{4}$$

Using the expected value for continuous random variables ($\rightarrow$ Definition I/1.5.1), the moment-generating function of X therefore is

$$\begin{aligned}
M_X(t) &= \int_{-\infty}^{+\infty} \exp[tx] \cdot \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \mathrm{d}x \\
&= \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{+\infty} \exp\left[tx - \frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \mathrm{d}x \ .
\end{aligned} \tag{5}$$

Substituting $u = (x-\mu)/(\sqrt{2}\sigma)$, i.e. $x = \sqrt{2}\sigma u + \mu$, we have

$$\begin{aligned}
M_X(t) &= \frac{1}{\sqrt{2\pi}\sigma} \int_{(-\infty-\mu)/(\sqrt{2}\sigma)}^{(+\infty-\mu)/(\sqrt{2}\sigma)} \exp\left[t\left(\sqrt{2}\sigma u + \mu\right) - \frac{1}{2}\left(\frac{\sqrt{2}\sigma u + \mu - \mu}{\sigma}\right)^2\right] \mathrm{d}\left(\sqrt{2}\sigma u + \mu\right) \\
&= \frac{\sqrt{2}\sigma}{\sqrt{2\pi}\sigma} \int_{-\infty}^{+\infty} \exp\left[\left(\sqrt{2}\sigma u + \mu\right)t - u^2\right] \mathrm{d}u \\
&= \frac{\exp(\mu t)}{\sqrt{\pi}} \int_{-\infty}^{+\infty} \exp\left[\sqrt{2}\sigma u t - u^2\right] \mathrm{d}u \\
&= \frac{\exp(\mu t)}{\sqrt{\pi}} \int_{-\infty}^{+\infty} \exp\left[-\left(u^2 - \sqrt{2}\sigma u t\right)\right] \mathrm{d}u \\
&= \frac{\exp(\mu t)}{\sqrt{\pi}} \int_{-\infty}^{+\infty} \exp\left[-\left(u - \frac{\sqrt{2}}{2}\sigma t\right)^2 + \frac{1}{2}\sigma^2 t^2\right] \mathrm{d}u \\
&= \frac{\exp\left[\mu t + \frac{1}{2}\sigma^2 t^2\right]}{\sqrt{\pi}} \int_{-\infty}^{+\infty} \exp\left[-\left(u - \frac{\sqrt{2}}{2}\sigma t\right)^2\right] \mathrm{d}u
\end{aligned} \tag{6}$$

Now substituting $v = u - \sqrt{2}/2\,\sigma t$, i.e. $u = v + \sqrt{2}/2\,\sigma t$, we have

$$\begin{aligned}
M_X(t) &= \frac{\exp\left[\mu t + \frac{1}{2}\sigma^2 t^2\right]}{\sqrt{\pi}} \int_{-\infty-\sqrt{2}/2\,\sigma t}^{+\infty-\sqrt{2}/2\,\sigma t} \exp\left[-v^2\right] \mathrm{d}\left(v + \sqrt{2}/2\,\sigma t\right) \\
&= \frac{\exp\left[\mu t + \frac{1}{2}\sigma^2 t^2\right]}{\sqrt{\pi}} \int_{-\infty}^{+\infty} \exp\left[-v^2\right] \mathrm{d}v \ .
\end{aligned} \tag{7}$$

With the Gaussian integral ($\rightarrow$ Proof II/3.2.6)

$$\int_{-\infty}^{+\infty} \exp\left[-x^2\right] \, \mathrm{d}x = \sqrt{\pi} \, , \tag{8}$$

this finally becomes

$$M_X(t) = \exp\left[\mu t + \frac{1}{2}\sigma^2 t^2\right] \, . \tag{9}$$

3.2.9 Cumulative distribution function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a normal distributions ($\rightarrow$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) \, . \tag{1}$$

Then, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of X is

$$F_X(x) = \frac{1}{2}\left[1 + \mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\right] \tag{2}$$

where $\mathrm{erf}(x)$ is the error function defined as

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}}\int_0^x \exp(-t^2)\,\mathrm{d}t \, . \tag{3}$$

Proof: The probability density function of the normal distribution ($\rightarrow$ Proof II/3.2.7) is:

$$f_X(x) = \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \, . \tag{4}$$

Thus, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) is:

$$\begin{aligned}
F_X(x) &= \int_{-\infty}^x \mathcal{N}(z; \mu, \sigma^2)\,\mathrm{d}z \\
&= \int_{-\infty}^x \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{z-\mu}{\sigma}\right)^2\right]\,\mathrm{d}z \\
&= \frac{1}{\sqrt{2\pi}\sigma}\int_{-\infty}^x \exp\left[-\left(\frac{z-\mu}{\sqrt{2}\sigma}\right)^2\right]\,\mathrm{d}z \, .
\end{aligned} \tag{5}$$

Substituting $t = (z-\mu)/(\sqrt{2}\sigma)$, i.e. $z = \sqrt{2}\sigma t + \mu$, this becomes:

$$F_X(x) = \frac{1}{\sqrt{2\pi}\sigma} \int_{(-\infty-\mu)/(\sqrt{2}\sigma)}^{(x-\mu)/(\sqrt{2}\sigma)} \exp(-t^2) \, \mathrm{d}\left(\sqrt{2}\sigma t + \mu\right)$$

$$= \frac{\sqrt{2}\sigma}{\sqrt{2\pi}\sigma} \int_{-\infty}^{\frac{x-\mu}{\sqrt{2}\sigma}} \exp(-t^2) \, \mathrm{d}t$$

$$= \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\frac{x-\mu}{\sqrt{2}\sigma}} \exp(-t^2) \, \mathrm{d}t \qquad (6)$$

$$= \frac{1}{\sqrt{\pi}} \int_{-\infty}^{0} \exp(-t^2) \, \mathrm{d}t + \frac{1}{\sqrt{\pi}} \int_{0}^{\frac{x-\mu}{\sqrt{2}\sigma}} \exp(-t^2) \, \mathrm{d}t$$

$$= \frac{1}{\sqrt{\pi}} \int_{0}^{\infty} \exp(-t^2) \, \mathrm{d}t + \frac{1}{\sqrt{\pi}} \int_{0}^{\frac{x-\mu}{\sqrt{2}\sigma}} \exp(-t^2) \, \mathrm{d}t \; .$$

Applying (3) to (6), we have:

$$F_X(x) = \frac{1}{2} \lim_{x\to\infty} \mathrm{erf}(x) + \frac{1}{2} \mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)$$

$$= \frac{1}{2} + \frac{1}{2} \mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right) \qquad (7)$$

$$= \frac{1}{2}\left[1 + \mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\right] \; .$$

3.2.10   Cumulative distribution function without error function

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a normal distribution ($\to$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) \; . \qquad (1)$$

Then, the cumulative distribution function ($\to$ Definition I/1.4.8) of X can be expressed as

$$f_X(x) = \Phi_{\mu,\sigma}(x) = \varphi\left(\frac{x-\mu}{\sigma}\right) \cdot \sum_{i=1}^{\infty} \frac{\left(\frac{x-\mu}{\sigma}\right)^{2i-1}}{(2i-1)!!} + \frac{1}{2} \qquad (2)$$

where $\varphi(x)$ is the probability density function ($\to$ Definition I/1.4.4) of the standard normal distribution ($\to$ Definition II/3.2.2) and $n!!$ is a double factorial.

Proof:

1) First, consider the standard normal distribution ($\rightarrow$ Definition II/3.2.2) $\mathcal{N}(0, 1)$ which has the probability density function ($\rightarrow$ Proof II/3.2.7)

$$\varphi(x) = \frac{1}{\sqrt{2\pi}} \cdot e^{-\frac{1}{2}x^2} \; . \tag{3}$$

Let $T(x)$ be the indefinite integral of this function. It can be obtained using infinitely repeated integration by parts as follows:

$$
\begin{aligned}
T(x) &= \int \varphi(x)\, \mathrm{d}x \\
&= \int \frac{1}{\sqrt{2\pi}} \cdot e^{-\frac{1}{2}x^2}\, \mathrm{d}x \\
&= \frac{1}{\sqrt{2\pi}} \int 1 \cdot e^{-\frac{1}{2}x^2}\, \mathrm{d}x \\
&= \frac{1}{\sqrt{2\pi}} \cdot \left[x \cdot e^{-\frac{1}{2}x^2} + \int x^2 \cdot e^{-\frac{1}{2}x^2}\, \mathrm{d}x \right] \\
&= \frac{1}{\sqrt{2\pi}} \cdot \left[x \cdot e^{-\frac{1}{2}x^2} + \left[\frac{1}{3}x^3 \cdot e^{-\frac{1}{2}x^2} + \int \frac{1}{3}x^4 \cdot e^{-\frac{1}{2}x^2}\, \mathrm{d}x \right] \right] \\
&= \frac{1}{\sqrt{2\pi}} \cdot \left[x \cdot e^{-\frac{1}{2}x^2} + \left[\frac{1}{3}x^3 \cdot e^{-\frac{1}{2}x^2} + \left[\frac{1}{15}x^5 \cdot e^{-\frac{1}{2}x^2} + \int \frac{1}{15}x^6 \cdot e^{-\frac{1}{2}x^2}\, \mathrm{d}x \right] \right] \right] \\
&= \dots \\
&= \frac{1}{\sqrt{2\pi}} \cdot \left[\sum_{i=1}^{n} \left(\frac{x^{2i-1}}{(2i-1)!!} \cdot e^{-\frac{1}{2}x^2} \right) + \int \left(\frac{x^{2n}}{(2n-1)!!} \cdot e^{-\frac{1}{2}x^2} \right) \mathrm{d}x \right] \\
&= \frac{1}{\sqrt{2\pi}} \cdot \left[\sum_{i=1}^{\infty} \left(\frac{x^{2i-1}}{(2i-1)!!} \cdot e^{-\frac{1}{2}x^2} \right) + \lim_{n\to\infty} \int \left(\frac{x^{2n}}{(2n-1)!!} \cdot e^{-\frac{1}{2}x^2} \right) \mathrm{d}x \right] \; .
\end{aligned}
\tag{4}
$$

Since $(2n-1)!!$ grows faster than x^{2n}, it holds that

$$\frac{1}{\sqrt{2\pi}} \cdot \lim_{n\to\infty} \int \left(\frac{x^{2n}}{(2n-1)!!} \cdot e^{-\frac{1}{2}x^2} \right) \mathrm{d}x = \int 0 \, \mathrm{d}x = c \tag{5}$$

for constant c, such that the indefinite integral becomes

$$
\begin{aligned}
T(x) &= \frac{1}{\sqrt{2\pi}} \cdot \sum_{i=1}^{\infty} \left(\frac{x^{2i-1}}{(2i-1)!!} \cdot e^{-\frac{1}{2}x^2} \right) + c \\
&= \frac{1}{\sqrt{2\pi}} \cdot e^{-\frac{1}{2}x^2} \cdot \sum_{i=1}^{\infty} \frac{x^{2i-1}}{(2i-1)!!} + c \\
&\overset{(3)}{=} \varphi(x) \cdot \sum_{i=1}^{\infty} \frac{x^{2i-1}}{(2i-1)!!} + c \; .
\end{aligned}
\tag{6}
$$

2) Next, let $\Phi(x)$ be the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of the standard normal distribution ($\rightarrow$ Definition II/3.2.2):

$$\Phi(x) = \int_{-\infty}^{x} \varphi(x)\, \mathrm{d}x \; . \tag{7}$$

It can be obtained by matching $T(0)$ to $\Phi(0)$ which is $1/2$, because the standard normal distribution is symmetric around zero:

$$T(0) = \varphi(0) \cdot \sum_{i=1}^{\infty} \frac{0^{2i-1}}{(2i-1)!!} + c = \frac{1}{2} = \Phi(0)$$

$$\Leftrightarrow c = \frac{1}{2} \tag{8}$$

$$\Rightarrow \Phi(x) = \varphi(x) \cdot \sum_{i=1}^{\infty} \frac{x^{2i-1}}{(2i-1)!!} + \frac{1}{2} .$$

3) Finally, the cumulative distribution functions ($\to$ Definition I/1.4.8) of the standard normal distribution ($\to$ Definition II/3.2.2) and the general normal distribution ($\to$ Definition II/3.2.1) are related to each other ($\to$ Proof II/3.2.3) as

$$\Phi_{\mu,\sigma}(x) = \Phi\left(\frac{x-\mu}{\sigma}\right) . \tag{9}$$

Combining (9) with (8), we have:

$$\Phi_{\mu,\sigma}(x) = \varphi\left(\frac{x-\mu}{\sigma}\right) \cdot \sum_{i=1}^{\infty} \frac{\left(\frac{x-\mu}{\sigma}\right)^{2i-1}}{(2i-1)!!} + \frac{1}{2} . \tag{10}$$

3.2.11   Quantile function

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a normal distributions ($\to$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) . \tag{1}$$

Then, the quantile function ($\to$ Definition I/1.4.17) of X is

$$Q_X(p) = \sqrt{2}\sigma \cdot \mathrm{erf}^{-1}(2p-1) + \mu \tag{2}$$

where $\mathrm{erf}^{-1}(x)$ is the inverse error function.

Proof: The cumulative distribution function of the normal distribution ($\to$ Proof II/3.2.9) is:

$$F_X(x) = \frac{1}{2}\left[1 + \mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\right] . \tag{3}$$

Because the cumulative distribution function (CDF) is strictly monotonically increasing, the quantile function is equal to the inverse of the CDF ($\to$ Proof I/1.4.18):

$$Q_X(p) = F_X^{-1}(x) \; . \tag{4}$$

This can be derived by rearranging equation (3):

$$
\begin{aligned}
p &= \frac{1}{2}\left[1 + \mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\right] \\
2p - 1 &= \mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right) \\
\mathrm{erf}^{-1}(2p-1) &= \frac{x-\mu}{\sqrt{2}\sigma} \\
x &= \sqrt{2}\sigma \cdot \mathrm{erf}^{-1}(2p-1) + \mu \; .
\end{aligned}
\tag{5}
$$

3.2.12 Mean

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a normal distribution ($\to$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) \; . \tag{1}$$

Then, the mean or expected value ($\to$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = \mu \; . \tag{2}$$

Proof: The expected value ($\to$ Definition I/1.5.1) is the probability-weighted average over all possible values:

$$\mathrm{E}(X) = \int_{\mathcal{X}} x \cdot f_X(x)\,\mathrm{d}x \; . \tag{3}$$

With the probability density function of the normal distribution ($\to$ Proof II/3.2.7), this reads:

$$
\begin{aligned}
\mathrm{E}(X) &= \int_{-\infty}^{+\infty} x \cdot \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]\,\mathrm{d}x \\
&= \frac{1}{\sqrt{2\pi}\sigma}\int_{-\infty}^{+\infty} x \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]\,\mathrm{d}x \; .
\end{aligned}
\tag{4}
$$

Substituting $z = x - \mu$, we have:

$$
\begin{aligned}
\mathrm{E}(X) &= \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty-\mu}^{+\infty-\mu} (z + \mu) \cdot \exp\left[-\frac{1}{2}\left(\frac{z}{\sigma}\right)^2\right] \mathrm{d}(z + \mu) \\
&= \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{+\infty} (z + \mu) \cdot \exp\left[-\frac{1}{2}\left(\frac{z}{\sigma}\right)^2\right] \mathrm{d}z \\
&= \frac{1}{\sqrt{2\pi}\sigma} \left(\int_{-\infty}^{+\infty} z \cdot \exp\left[-\frac{1}{2}\left(\frac{z}{\sigma}\right)^2\right] \mathrm{d}z + \mu \int_{-\infty}^{+\infty} \exp\left[-\frac{1}{2}\left(\frac{z}{\sigma}\right)^2\right] \mathrm{d}z \right) \\
&= \frac{1}{\sqrt{2\pi}\sigma} \left(\int_{-\infty}^{+\infty} z \cdot \exp\left[-\frac{1}{2\sigma^2} \cdot z^2\right] \mathrm{d}z + \mu \int_{-\infty}^{+\infty} \exp\left[-\frac{1}{2\sigma^2} \cdot z^2\right] \mathrm{d}z \right) \, .
\end{aligned}
\tag{5}
$$

The general antiderivatives are

$$
\begin{aligned}
\int x \cdot \exp\left[-ax^2\right] \mathrm{d}x &= -\frac{1}{2a} \cdot \exp\left[-ax^2\right] \\
\int \exp\left[-ax^2\right] \mathrm{d}x &= \frac{1}{2}\sqrt{\frac{\pi}{a}} \cdot \mathrm{erf}\left[\sqrt{a}x\right]
\end{aligned}
\tag{6}
$$

where $\mathrm{erf}(x)$ is the error function. Using this, the integrals can be calculated as:

$$
\begin{aligned}
\mathrm{E}(X) &= \frac{1}{\sqrt{2\pi}\sigma} \left(\left[-\sigma^2 \cdot \exp\left[-\frac{1}{2\sigma^2} \cdot z^2\right]\right]_{-\infty}^{+\infty} + \mu \left[\sqrt{\frac{\pi}{2}}\sigma \cdot \mathrm{erf}\left[\frac{1}{\sqrt{2}\sigma}z\right]\right]_{-\infty}^{+\infty} \right) \\
&= \frac{1}{\sqrt{2\pi}\sigma} \left(\left[\lim_{z\to\infty}\left(-\sigma^2 \cdot \exp\left[-\frac{1}{2\sigma^2} \cdot z^2\right]\right) - \lim_{z\to-\infty}\left(-\sigma^2 \cdot \exp\left[-\frac{1}{2\sigma^2} \cdot z^2\right]\right)\right] \right. \\
&\qquad \left. + \mu \left[\lim_{z\to\infty}\left(\sqrt{\frac{\pi}{2}}\sigma \cdot \mathrm{erf}\left[\frac{1}{\sqrt{2}\sigma}z\right]\right) - \lim_{z\to-\infty}\left(\sqrt{\frac{\pi}{2}}\sigma \cdot \mathrm{erf}\left[\frac{1}{\sqrt{2}\sigma}z\right]\right)\right] \right) \\
&= \frac{1}{\sqrt{2\pi}\sigma} \left([0 - 0] + \mu \left[\sqrt{\frac{\pi}{2}}\sigma - \left(-\sqrt{\frac{\pi}{2}}\sigma\right)\right] \right) \\
&= \frac{1}{\sqrt{2\pi}\sigma} \cdot \mu \cdot 2\sqrt{\frac{\pi}{2}}\sigma \\
&= \mu \, .
\end{aligned}
\tag{7}
$$

3.2.13 Median

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a normal distribution ($\rightarrow$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) \,. \tag{1}$$

Then, the median ($\rightarrow$ Definition I/1.9.1) of X is

$$\text{median}(X) = \mu \,. \tag{2}$$

Proof: The median ($\rightarrow$ Definition I/1.9.1) is the value at which the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) is $1/2$:

$$F_X(\text{median}(X)) = \frac{1}{2} \,. \tag{3}$$

The cumulative distribution function of the normal distribution ($\rightarrow$ Proof II/3.2.9) is

$$F_X(x) = \frac{1}{2} \left[1 + \text{erf}\left(\frac{x - \mu}{\sqrt{2}\sigma} \right) \right] \tag{4}$$

where $\text{erf}(x)$ is the error function. Thus, the inverse CDF is

$$x = \sqrt{2}\sigma \cdot \text{erf}^{-1}(2p - 1) + \mu \tag{5}$$

where $\text{erf}^{-1}(x)$ is the inverse error function. Setting $p = 1/2$, we obtain:

$$\text{median}(X) = \sqrt{2}\sigma \cdot \text{erf}^{-1}(0) + \mu = \mu \,. \tag{6}$$

- original work

Metadata: ID: P16 | shortcut: norm-med | author: JoramSoch | date: 2020-01-09, 15:33.

3.2.14 Mode

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a normal distribution ($\rightarrow$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) \,. \tag{1}$$

Then, the mode ($\rightarrow$ Definition I/1.9.2) of X is

$$\text{mode}(X) = \mu \,. \tag{2}$$

Proof: The mode ($\rightarrow$ Definition I/1.9.2) is the value which maximizes the probability density function ($\rightarrow$ Definition I/1.4.4):

$$\text{mode}(X) = \arg\max_x f_X(x) \,. \tag{3}$$

The probability density function of the normal distribution ($\rightarrow$ Proof II/3.2.7) is:

$$f_X(x) = \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2} \left(\frac{x - \mu}{\sigma} \right)^2 \right] \,. \tag{4}$$

The first two deriatives of this function are:

$$f'_X(x) = \frac{\mathrm{d}f_X(x)}{\mathrm{d}x} = \frac{1}{\sqrt{2\pi}\sigma^3} \cdot (-x + \mu) \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \tag{5}$$

$$f''_X(x) = \frac{\mathrm{d}^2 f_X(x)}{\mathrm{d}x^2} = -\frac{1}{\sqrt{2\pi}\sigma^3}\cdot\exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] + \frac{1}{\sqrt{2\pi}\sigma^5}\cdot(-x+\mu)^2\cdot\exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] . \tag{6}$$

We now calculate the root of the first derivative (5):

$$\begin{aligned}
f'_X(x) = 0 &= \frac{1}{\sqrt{2\pi}\sigma^3} \cdot (-x + \mu) \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \\
0 &= -x + \mu \\
x &= \mu .
\end{aligned} \tag{7}$$

By plugging this value into the second deriative (6),

$$\begin{aligned}
f''_X(\mu) &= -\frac{1}{\sqrt{2\pi}\sigma^3} \cdot \exp(0) + \frac{1}{\sqrt{2\pi}\sigma^5} \cdot (0)^2 \cdot \exp(0) \\
&= -\frac{1}{\sqrt{2\pi}\sigma^3} < 0 ,
\end{aligned} \tag{8}$$

we confirm that it is in fact a maximum which shows that

$$\mathrm{mode}(X) = \mu . \tag{9}$$

3.2.15   Variance

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a normal distribution ($\to$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) . \tag{1}$$

Then, the variance ($\to$ Definition I/1.6.1) of X is

$$\mathrm{Var}(X) = \sigma^2 . \tag{2}$$

Proof: The variance ($\to$ Definition I/1.6.1) is the probability-weighted average of the squared deviation from the mean ($\to$ Definition I/1.5.1):

$$\mathrm{Var}(X) = \int_{\mathbb{R}} (x - \mathrm{E}(X))^2 \cdot f_X(x)\, \mathrm{d}x \ . \tag{3}$$

With the expected value ($\to$ Proof II/3.2.12) and probability density function ($\to$ Proof II/3.2.7) of the normal distribution, this reads:

$$
\begin{aligned}
\mathrm{Var}(X) &= \int_{-\infty}^{+\infty} (x - \mu)^2 \cdot \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \mathrm{d}x \\
&= \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{+\infty} (x-\mu)^2 \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \mathrm{d}x \ .
\end{aligned}
\tag{4}
$$

Substituting $z = x - \mu$, we have:

$$
\begin{aligned}
\mathrm{Var}(X) &= \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty-\mu}^{+\infty-\mu} z^2 \cdot \exp\left[-\frac{1}{2}\left(\frac{z}{\sigma}\right)^2\right] \mathrm{d}(z + \mu) \\
&= \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{+\infty} z^2 \cdot \exp\left[-\frac{1}{2}\left(\frac{z}{\sigma}\right)^2\right] \mathrm{d}z \ .
\end{aligned}
\tag{5}
$$

Now substituting $z = \sqrt{2}\sigma x$, we have:

$$
\begin{aligned}
\mathrm{Var}(X) &= \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{+\infty} (\sqrt{2}\sigma x)^2 \cdot \exp\left[-\frac{1}{2}\left(\frac{\sqrt{2}\sigma x}{\sigma}\right)^2\right] \mathrm{d}(\sqrt{2}\sigma x) \\
&= \frac{1}{\sqrt{2\pi}\sigma} \cdot 2\sigma^2 \cdot \sqrt{2}\sigma \int_{-\infty}^{+\infty} x^2 \cdot \exp\left[-x^2\right] \mathrm{d}x \\
&= \frac{2\sigma^2}{\sqrt{\pi}} \int_{-\infty}^{+\infty} x^2 \cdot e^{-x^2} \mathrm{d}x \ .
\end{aligned}
\tag{6}
$$

Since the integrand is symmetric with respect to $x = 0$, we can write:

$$\mathrm{Var}(X) = \frac{4\sigma^2}{\sqrt{\pi}} \int_0^\infty x^2 \cdot e^{-x^2} \mathrm{d}x \ . \tag{7}$$

If we define $z = x^2$, then $x = \sqrt{z}$ and $\mathrm{d}x = 1/2\, z^{-1/2}\, \mathrm{d}z$. Substituting this into the integral

$$\mathrm{Var}(X) = \frac{4\sigma^2}{\sqrt{\pi}} \int_0^\infty z \cdot e^{-z} \cdot \frac{1}{2} z^{-\frac{1}{2}}\, \mathrm{d}z = \frac{2\sigma^2}{\sqrt{\pi}} \int_0^\infty z^{\frac{3}{2}-1} \cdot e^{-z}\, \mathrm{d}z \tag{8}$$

and using the definition of the gamma function

$$\Gamma(x) = \int_0^\infty z^{x-1} \cdot e^{-z}\, \mathrm{d}z \ , \tag{9}$$

we can finally show that

$$\mathrm{Var}(X) = \frac{2\sigma^2}{\sqrt{\pi}} \cdot \Gamma\left(\frac{3}{2}\right) = \frac{2\sigma^2}{\sqrt{\pi}} \cdot \frac{\sqrt{\pi}}{2} = \sigma^2 \ . \tag{10}$$

3.2.16 Full width at half maximum

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a normal distribution ($\to$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) \; . \tag{1}$$

Then, the full width at half maximum ($\to$ Definition I/1.10.2) (FWHM) of X is

$$\mathrm{FWHM}(X) = 2\sqrt{2\ln 2}\,\sigma \; . \tag{2}$$

Proof: The probability density function of the normal distribution ($\to$ Proof II/3.2.7) is

$$f_X(x) = \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2 \right] \tag{3}$$

and the mode of the normal distribution ($\to$ Proof II/3.2.14) is

$$\mathrm{mode}(X) = \mu \; , \tag{4}$$

such that

$$f_{\max} = f_X(\mathrm{mode}(X)) \overset{(4)}{=} f_X(\mu) \overset{(3)}{=} \frac{1}{\sqrt{2\pi}\sigma} \; . \tag{5}$$

The FWHM bounds satisfy the equation ($\to$ Definition I/1.10.2)

$$f_X(x_{\mathrm{FWHM}}) = \frac{1}{2} f_{\max} \overset{(5)}{=} \frac{1}{2\sqrt{2\pi}\sigma} \; . \tag{6}$$

Using (3), we can develop this equation as follows:

$$\frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x_{\mathrm{FWHM}} - \mu}{\sigma}\right)^2\right] = \frac{1}{2\sqrt{2\pi}\sigma}$$

$$\exp\left[-\frac{1}{2}\left(\frac{x_{\mathrm{FWHM}} - \mu}{\sigma}\right)^2\right] = \frac{1}{2}$$

$$-\frac{1}{2}\left(\frac{x_{\mathrm{FWHM}} - \mu}{\sigma}\right)^2 = \ln\frac{1}{2} \tag{7}$$

$$\left(\frac{x_{\mathrm{FWHM}} - \mu}{\sigma}\right)^2 = -2\ln\frac{1}{2}$$

$$\frac{x_{\mathrm{FWHM}} - \mu}{\sigma} = \pm\sqrt{2\ln 2}$$

$$x_{\mathrm{FWHM}} - \mu = \pm\sqrt{2\ln 2}\sigma$$

$$x_{\mathrm{FWHM}} = \pm\sqrt{2\ln 2}\sigma + \mu \;.$$

This implies the following two solutions for x_{FWHM}

$$x_1 = \mu - \sqrt{2\ln 2}\sigma$$
$$x_2 = \mu + \sqrt{2\ln 2}\sigma \;, \tag{8}$$

such that the full width at half maximum ($\rightarrow$ Definition I/1.10.2) of X is

$$\mathrm{FWHM}(X) = \Delta x = x_2 - x_1$$
$$\overset{(8)}{=} \left(\mu + \sqrt{2\ln 2}\sigma\right) - \left(\mu - \sqrt{2\ln 2}\sigma\right) \tag{9}$$
$$= 2\sqrt{2\ln 2}\sigma \;.$$

3.2.17 Differential entropy

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a normal distribution ($\rightarrow$ Definition II/3.2.1):

$$X \sim \mathcal{N}(\mu, \sigma^2) \;. \tag{1}$$

Then, the differential entropy ($\rightarrow$ Definition I/2.2.1) of X is

$$\mathrm{h}(X) = \frac{1}{2}\ln\left(2\pi\sigma^2 e\right) \;. \tag{2}$$

Proof: The differential entropy ($\rightarrow$ Definition I/2.2.1) of a random variable is defined as

$$\mathrm{h}(X) = -\int_{\mathcal{X}} p(x) \log_b p(x) \, \mathrm{d}x \; . \tag{3}$$

To measure $h(X)$ in nats, we set $b = e$, such that ($\rightarrow$ Definition I/1.5.1)

$$\mathrm{h}(X) = -\mathrm{E}\left[\ln p(x)\right] \; . \tag{4}$$

With the probability density function of the normal distribution ($\rightarrow$ Proof II/3.2.7), the differential entropy of X is:

$$
\begin{aligned}
\mathrm{h}(X) &= -\mathrm{E}\left[\ln\left(\frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]\right)\right] \\
&= -\mathrm{E}\left[-\frac{1}{2}\ln(2\pi\sigma^2) - \frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \\
&= \frac{1}{2}\ln(2\pi\sigma^2) + \frac{1}{2}\,\mathrm{E}\left[\left(\frac{x-\mu}{\sigma}\right)^2\right] \\
&= \frac{1}{2}\ln(2\pi\sigma^2) + \frac{1}{2} \cdot \frac{1}{\sigma^2} \cdot \mathrm{E}\left[(x-\mu)^2\right] \\
&= \frac{1}{2}\ln(2\pi\sigma^2) + \frac{1}{2} \cdot \frac{1}{\sigma^2} \cdot \sigma^2 \\
&= \frac{1}{2}\ln(2\pi\sigma^2) + \frac{1}{2} \\
&= \frac{1}{2}\ln(2\pi\sigma^2 e) \; .
\end{aligned}
\tag{5}
$$

3.2.18 Kullback-Leibler divergence

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3). Assume two normal distributions ($\rightarrow$ Definition II/3.2.1) P and Q specifying the probability distribution of X as

$$
\begin{aligned}
P &: \; X \sim \mathcal{N}(\mu_1, \sigma_1^2) \\
Q &: \; X \sim \mathcal{N}(\mu_2, \sigma_2^2) \; .
\end{aligned}
\tag{1}
$$

Then, the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) of P from Q is given by

$$\mathrm{KL}[P \,\|\, Q] = \frac{1}{2}\left[\frac{(\mu_2 - \mu_1)^2}{\sigma_2^2} + \frac{\sigma_1^2}{\sigma_2^2} - \ln\frac{\sigma_1^2}{\sigma_2^2} - 1\right] \; . \tag{2}$$

Proof: The KL divergence for a continuous random variable ($\rightarrow$ Definition I/2.5.1) is given by

$$\mathrm{KL}[P \,||\, Q] = \int_{\mathcal{X}} p(x) \ln \frac{p(x)}{q(x)} \, \mathrm{d}x \tag{3}$$

which, applied to the normal distributions ($\rightarrow$ Definition II/3.2.1) in (1), yields

$$
\begin{aligned}
\mathrm{KL}[P \,||\, Q] &= \int_{-\infty}^{+\infty} \mathcal{N}(x; \mu_1, \sigma_1^2) \ln \frac{\mathcal{N}(x; \mu_1, \sigma_1^2)}{\mathcal{N}(x; \mu_2, \sigma_2^2)} \, \mathrm{d}x \\
&= \left\langle \ln \frac{\mathcal{N}(x; \mu_1, \sigma_1^2)}{\mathcal{N}(x; \mu_2, \sigma_2^2)} \right\rangle_{p(x)} .
\end{aligned}
\tag{4}
$$

Using the probability density function of the normal distribution ($\rightarrow$ Proof II/3.2.7), this becomes:

$$
\begin{aligned}
\mathrm{KL}[P \,||\, Q] &= \left\langle \ln \frac{\frac{1}{\sqrt{2\pi}\sigma_1} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu_1}{\sigma_1}\right)^2\right]}{\frac{1}{\sqrt{2\pi}\sigma_2} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu_2}{\sigma_2}\right)^2\right]} \right\rangle_{p(x)} \\
&= \left\langle \ln \left(\sqrt{\frac{\sigma_2^2}{\sigma_1^2}} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu_1}{\sigma_1}\right)^2 + \frac{1}{2}\left(\frac{x-\mu_2}{\sigma_2}\right)^2\right] \right) \right\rangle_{p(x)} \\
&= \left\langle \frac{1}{2}\ln \frac{\sigma_2^2}{\sigma_1^2} - \frac{1}{2}\left(\frac{x-\mu_1}{\sigma_1}\right)^2 + \frac{1}{2}\left(\frac{x-\mu_2}{\sigma_2}\right)^2 \right\rangle_{p(x)} \\
&= \frac{1}{2}\left\langle -\left(\frac{x-\mu_1}{\sigma_1}\right)^2 + \left(\frac{x-\mu_2}{\sigma_2}\right)^2 - \ln \frac{\sigma_1^2}{\sigma_2^2} \right\rangle_{p(x)} \\
&= \frac{1}{2}\left\langle -\frac{(x-\mu_1)^2}{\sigma_1^2} + \frac{x^2 - 2\mu_2 x + \mu_2^2}{\sigma_2^2} - \ln \frac{\sigma_1^2}{\sigma_2^2} \right\rangle_{p(x)} .
\end{aligned}
\tag{5}
$$

Because the expected value ($\rightarrow$ Definition I/1.5.1) is a linear operator ($\rightarrow$ Proof I/1.5.5), the expectation can be moved into the sum:

$$
\begin{aligned}
\mathrm{KL}[P \,||\, Q] &= \frac{1}{2}\left[-\frac{\langle (x-\mu_1)^2 \rangle}{\sigma_1^2} + \frac{\langle x^2 - 2\mu_2 x + \mu_2^2 \rangle}{\sigma_2^2} - \left\langle \ln \frac{\sigma_1^2}{\sigma_2^2} \right\rangle \right] \\
&= \frac{1}{2}\left[-\frac{\langle (x-\mu_1)^2 \rangle}{\sigma_1^2} + \frac{\langle x^2 \rangle - \langle 2\mu_2 x \rangle + \langle \mu_2^2 \rangle}{\sigma_2^2} - \ln \frac{\sigma_1^2}{\sigma_2^2} \right] .
\end{aligned}
\tag{6}
$$

The first expectation corresponds to the variance ($\rightarrow$ Definition I/1.6.1)

$$\left\langle (X - \mu)^2 \right\rangle = \mathrm{E}[(X - \mathrm{E}(X))^2] = \mathrm{Var}(X) \tag{7}$$

and the variance of a normally distributed random variable ($\rightarrow$ Proof II/3.2.15) is

$$X \sim \mathcal{N}(\mu, \sigma^2) \quad \Rightarrow \quad \mathrm{Var}(X) = \sigma^2 . \tag{8}$$

Additionally applying the raw moments of the normal distribution ($\rightarrow$ Proof II/3.2.8)

$$ X \sim \mathcal{N}(\mu, \sigma^2) \quad \Rightarrow \quad \langle x \rangle = \mu \quad \text{and} \quad \langle x^2 \rangle = \mu^2 + \sigma^2 \;, \tag{9} $$

the Kullback-Leibler divergence in (6) becomes

$$
\begin{aligned}
\mathrm{KL}[P \,\|\, Q] &= \frac{1}{2} \left[-\frac{\sigma_1^2}{\sigma_1^2} + \frac{\mu_1^2 + \sigma_1^2 - 2\mu_2\mu_1 + \mu_2^2}{\sigma_2^2} - \ln\frac{\sigma_1^2}{\sigma_2^2} \right] \\
&= \frac{1}{2} \left[\frac{\mu_1^2 - 2\mu_1\mu_2 + \mu_2^2}{\sigma_2^2} + \frac{\sigma_1^2}{\sigma_2^2} - \ln\frac{\sigma_1^2}{\sigma_2^2} - 1 \right] \\
&= \frac{1}{2} \left[\frac{(\mu_1 - \mu_2)^2}{\sigma_2^2} + \frac{\sigma_1^2}{\sigma_2^2} - \ln\frac{\sigma_1^2}{\sigma_2^2} - 1 \right]
\end{aligned}
\tag{10}
$$

which is equivalent to (2).

3.3   t-distribution

3.3.1   Definition

Definition: Let $X_1, ..., X_n$ be independent ($\rightarrow$ Definition I/1.2.6) random variables ($\rightarrow$ Definition I/1.1.3) where each of them is following a normal distribution ($\rightarrow$ Definition II/3.2.1) with mean μ and variance σ^2:

$$ X_i \sim \mathcal{N}(\mu, \sigma^2) \quad \text{for} \quad i = 1, \ldots, n \;. \tag{1} $$

Then, the following random variable with sample mean ($\rightarrow$ Definition I/1.5.2) $\bar{X}$ and sample variance ($\rightarrow$ Definition I/1.6.2) s^2 is said to be t-distributed with $n-1$ degrees of freedom:

$$ Y = \frac{\bar{X} - \mu}{s/\sqrt{n}} \sim t(n-1) \;. \tag{2} $$

The t-distribution is also called "Student's t-distribution", after William S. Gosset a.k.a. "Student".

3.4   Gamma distribution

3.4.1   Definition

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3). Then, X is said to follow a gamma distribution with shape a and rate b

$$X \sim \mathrm{Gam}(a, b) \ , \tag{1}$$

if and only if its probability density function ($\rightarrow$ Definition I/1.4.4) is given by

$$\mathrm{Gam}(x; a, b) = \frac{b^a}{\Gamma(a)} x^{a-1} \exp[-bx], \quad x > 0 \tag{2}$$

where $a > 0$ and $b > 0$, and the density is zero, if $x \leq 0$.

3.4.2 Standard gamma distribution

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3). Then, X is said to have a standard gamma distribution, if X follows a gamma distribution ($\rightarrow$ Definition II/3.4.1) with shape $a > 0$ and rate $b = 1$:

$$X \sim \mathrm{Gam}(a, 1) \ . \tag{1}$$

3.4.3 Relation to standard gamma distribution

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a gamma distribution ($\rightarrow$ Definition II/3.4.1) with shape a and rate b:

$$X \sim \mathrm{Gam}(a, b) \ . \tag{1}$$

Then, the quantity $Y = bX$ will have a standard gamma distribution ($\rightarrow$ Definition II/3.4.2) with shape a and rate 1:

$$Y = bX \sim \mathrm{Gam}(a, 1) \ . \tag{2}$$

Proof: Note that Y is a function of X

$$Y = g(X) = bX \tag{3}$$

with the inverse function

$$X = g^{-1}(Y) = \frac{1}{b}Y \; . \tag{4}$$

Because b is positive, $g(X)$ is strictly increasing and we can calculate the cumulative distribution function of a strictly increasing function ($\rightarrow$ Proof I/1.4.9) as

$$F_Y(y) = \begin{cases} 0 \; , & \text{if } y < \min(\mathcal{Y}) \\ F_X(g^{-1}(y)) \; , & \text{if } y \in \mathcal{Y} \\ 1 \; , & \text{if } y > \max(\mathcal{Y}) \; . \end{cases} \tag{5}$$

The cumulative distribution function of the gamma-distributed ($\rightarrow$ Proof II/3.4.6) X is

$$F_X(x) = \int_{-\infty}^{x} \frac{b^a}{\Gamma(a)} t^{a-1} \exp[-bt] \, \mathrm{d}t \; . \tag{6}$$

Applying (5) to (6), we have:

$$\begin{aligned} F_Y(y) &\overset{(5)}{=} F_X(g^{-1}(y)) \\ &\overset{(6)}{=} \int_{-\infty}^{y/b} \frac{b^a}{\Gamma(a)} t^{a-1} \exp[-bt] \, \mathrm{d}t \; . \end{aligned} \tag{7}$$

Substituting $s = bt$, such that $t = s/b$, we obtain

$$\begin{aligned} F_Y(y) &= \int_{-b\infty}^{b(y/b)} \frac{b^a}{\Gamma(a)} \left(\frac{s}{b}\right)^{a-1} \exp\left[-b\left(\frac{s}{b}\right)\right] \, \mathrm{d}\left(\frac{s}{b}\right) \\ &= \int_{-\infty}^{y} \frac{b^a}{\Gamma(a)} \frac{1}{b^{a-1} b} s^{a-1} \exp[-s] \, \mathrm{d}s \\ &= \int_{-\infty}^{y} \frac{1}{\Gamma(a)} s^{a-1} \exp[-s] \, \mathrm{d}s \end{aligned} \tag{8}$$

which is the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of the standard gamma distribution ($\rightarrow$ Definition II/3.4.2).

3.4.4 Relation to standard gamma distribution

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a gamma distribution ($\rightarrow$ Definition II/3.4.1) with shape a and rate b:

$$X \sim \mathrm{Gam}(a, b) \; . \tag{1}$$

Then, the quantity $Y = bX$ will have a standard gamma distribution ($\rightarrow$ Definition II/3.4.2) with shape a and rate 1:

$$Y = bX \sim \text{Gam}(a, 1) \; . \tag{2}$$

Proof: Note that Y is a function of X

$$Y = g(X) = bX \tag{3}$$

with the inverse function

$$X = g^{-1}(Y) = \frac{1}{b}Y \; . \tag{4}$$

Because b is positive, $g(X)$ is strictly increasing and we can calculate the probability density function of a strictly increasing function ($\rightarrow$ Proof I/1.4.5) as

$$f_Y(y) = \begin{cases} f_X(g^{-1}(y)) \, \frac{\mathrm{d}g^{-1}(y)}{\mathrm{d}y} \; , & \text{if } y \in \mathcal{Y} \\ 0 \; , & \text{if } y \notin \mathcal{Y} \end{cases} \tag{5}$$

where $\mathcal{Y} = \{y = g(x) : x \in \mathcal{X}\}$. With the probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5), we have

$$\begin{aligned} f_Y(y) &= \frac{b^a}{\Gamma(a)} [g^{-1}(y)]^{a-1} \exp[-b \, g^{-1}(y)] \cdot \frac{\mathrm{d}g^{-1}(y)}{\mathrm{d}y} \\ &= \frac{b^a}{\Gamma(a)} \left(\frac{1}{b}y\right)^{a-1} \exp\left[-b\left(\frac{1}{b}y\right)\right] \cdot \frac{\mathrm{d}\left(\frac{1}{b}y\right)}{\mathrm{d}y} \\ &= \frac{b^a}{\Gamma(a)} \frac{1}{b^{a-1}} y^{a-1} \exp[-y] \cdot \frac{1}{b} \\ &= \frac{1}{\Gamma(a)} y^{a-1} \exp[-y] \end{aligned} \tag{6}$$

which is the probability density function ($\rightarrow$ Definition I/1.4.4) of the standard gamma distribution ($\rightarrow$ Definition II/3.4.2).

3.4.5 Probability density function

Theorem: Let X be a positive random variable ($\rightarrow$ Definition I/1.1.3) following a gamma distribution ($\rightarrow$ Definition II/3.4.1):

$$X \sim \text{Gam}(a, b) \; . \tag{1}$$

Then, the probability density function ($\rightarrow$ Definition I/1.4.4) of X is

$$f_X(x) = \frac{b^a}{\Gamma(a)} x^{a-1} \exp[-bx] \;. \tag{2}$$

Proof: This follows directly from the definition of the gamma distribution ($\rightarrow$ Definition II/3.4.1).

Sources:
- original work

Metadata: ID: P45 | shortcut: gam-pdf | author: JoramSoch | date: 2020-02-08, 23:41.

3.4.6   Cumulative distribution function

Theorem: Let X be a positive random variable ($\rightarrow$ Definition I/1.1.3) following a gamma distribution ($\rightarrow$ Definition II/3.4.1):

$$X \sim \mathrm{Gam}(a, b) \;. \tag{1}$$

Then, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of X is

$$F_X(x) = \frac{\gamma(a, bx)}{\Gamma(a)} \tag{2}$$

where $\Gamma(x)$ is the gamma function and $\gamma(s, x)$ is the lower incomplete gamma function.

Proof: The probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5) is:

$$f_X(x) = \frac{b^a}{\Gamma(a)} x^{a-1} \exp[-bx] \;. \tag{3}$$

Thus, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) is:

$$
\begin{aligned}
F_X(x) &= \int_0^x \mathrm{Gam}(z; a, b) \, \mathrm{d}z \\
&= \int_0^x \frac{b^a}{\Gamma(a)} z^{a-1} \exp[-bz] \, \mathrm{d}z \\
&= \frac{b^a}{\Gamma(a)} \int_0^x z^{a-1} \exp[-bz] \, \mathrm{d}z \;.
\end{aligned}
\tag{4}
$$

Substituting $t = bz$, i.e. $z = t/b$, this becomes:

$$
\begin{aligned}
F_X(x) &= \frac{b^a}{\Gamma(a)} \int_{b \cdot 0}^{bx} \left(\frac{t}{b}\right)^{a-1} \exp\left[-b\left(\frac{t}{b}\right)\right] \, \mathrm{d}\left(\frac{t}{b}\right) \\
&= \frac{b^a}{\Gamma(a)} \cdot \frac{1}{b^{a-1}} \cdot \frac{1}{b} \int_0^{bx} t^{a-1} \exp[-t] \, \mathrm{d}t \\
&= \frac{1}{\Gamma(a)} \int_0^{bx} t^{a-1} \exp[-t] \, \mathrm{d}t \;.
\end{aligned}
\tag{5}
$$

With the definition of the lower incomplete gamma function

$$\gamma(s, x) = \int_0^x t^{s-1} \exp[-t] \, \mathrm{d}t , \tag{6}$$

we arrive at the final result given by equation (2):

$$F_X(x) = \frac{\gamma(a, bx)}{\Gamma(a)} . \tag{7}$$

Sources:
- Wikipedia (2020): "Incomplete gamma function"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-10-29; URL: https://en.wikipedia.org/wiki/Incomplete_gamma_function#Definition.

Metadata: ID: P178 | shortcut: gam-cdf | author: JoramSoch | date: 2020-10-15, 12:34.

3.4.7 Quantile function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a gamma distribution ($\rightarrow$ Definition II/3.4.1):

$$X \sim \mathrm{Gam}(a, b) . \tag{1}$$

Then, the quantile function ($\rightarrow$ Definition I/1.4.17) of X is

$$Q_X(p) = \begin{cases} -\infty , & \text{if } p = 0 \\ \gamma^{-1}(a, \Gamma(a) \cdot p)/b , & \text{if } p > 0 \end{cases} \tag{2}$$

where $\gamma^{-1}(s, y)$ is the inverse of the lower incomplete gamma function $\gamma(s, x)$

Proof: The cumulative distribution function of the gamma distribution ($\rightarrow$ Proof II/3.4.6) is:

$$F_X(x) = \begin{cases} 0 , & \text{if } x < 0 \\ \frac{\gamma(a, bx)}{\Gamma(a)} , & \text{if } x \geq 0 . \end{cases} \tag{3}$$

The quantile function $Q_X(p)$ is defined as ($\rightarrow$ Definition I/1.4.17) the smallest x, such that $F_X(x) = p$:

$$Q_X(p) = \min \{x \in \mathbb{R} \,|\, F_X(x) = p\} . \tag{4}$$

Thus, we have $Q_X(p) = -\infty$, if $p = 0$. When $p > 0$, it holds that ($\rightarrow$ Proof I/1.4.18)

$$Q_X(p) = F_X^{-1}(x) . \tag{5}$$

This can be derived by rearranging equation (3):

$$\begin{aligned} p &= \frac{\gamma(a, bx)}{\Gamma(a)} \\ \Gamma(a) \cdot p &= \gamma(a, bx) \\ \gamma^{-1}(a, \Gamma(a) \cdot p) &= bx \\ x &= \frac{\gamma^{-1}(a, \Gamma(a) \cdot p)}{b} . \end{aligned} \tag{6}$$

Sources:
- Wikipedia (2020): "Incomplete gamma function"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-11-19; URL: https://en.wikipedia.org/wiki/Incomplete_gamma_function#Definition.

Metadata: ID: P194 | shortcut: gam-qf | author: JoramSoch | date: 2020-11-19, 07:31.

3.4.8 Mean

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a gamma distribution ($\rightarrow$ Definition II/3.4.1):

$$X \sim \mathrm{Gam}(a, b) \ . \tag{1}$$

Then, the mean or expected value ($\rightarrow$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = \frac{a}{b} \ . \tag{2}$$

Proof: The expected value ($\rightarrow$ Definition I/1.5.1) is the probability-weighted average over all possible values:

$$\mathrm{E}(X) = \int_{\mathcal{X}} x \cdot f_X(x) \, \mathrm{d}x \ . \tag{3}$$

With the probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5), this reads:

$$
\begin{aligned}
\mathrm{E}(X) &= \int_0^\infty x \cdot \frac{b^a}{\Gamma(a)} x^{a-1} \exp[-bx] \, \mathrm{d}x \\
&= \int_0^\infty \frac{b^a}{\Gamma(a)} x^{(a+1)-1} \exp[-bx] \, \mathrm{d}x \\
&= \int_0^\infty \frac{1}{b} \cdot \frac{b^{a+1}}{\Gamma(a)} x^{(a+1)-1} \exp[-bx] \, \mathrm{d}x \ .
\end{aligned}
\tag{4}
$$

Employing the relation $\Gamma(x+1) = \Gamma(x) \cdot x$, we have

$$\mathrm{E}(X) = \int_0^\infty \frac{a}{b} \cdot \frac{b^{a+1}}{\Gamma(a+1)} x^{(a+1)-1} \exp[-bx] \, \mathrm{d}x \tag{5}$$

and again using the density of the gamma distribution ($\rightarrow$ Proof II/3.4.5), we get

$$
\begin{aligned}
\mathrm{E}(X) &= \frac{a}{b} \int_0^\infty \mathrm{Gam}(x; a+1, b) \, \mathrm{d}x \\
&= \frac{a}{b} \ .
\end{aligned}
\tag{6}
$$

- Turlapaty, Anish (2013): "Gamma random variable: mean & variance"; in: *YouTube*, retrieved on 2020-05-19; URL: https://www.youtube.com/watch?v=Sy4wP-Y2dmA.

Metadata: ID: P108 | shortcut: gam-mean | author: JoramSoch | date: 2020-05-19, 06:54.

3.4.9 Variance

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a gamma distribution ($\rightarrow$ Definition II/3.4.1):

$$X \sim \text{Gam}(a, b) \ . \tag{1}$$

Then, the variance ($\rightarrow$ Definition I/1.6.1) of X is

$$\text{Var}(X) = \frac{a}{b^2} \ . \tag{2}$$

Proof: The variance ($\rightarrow$ Definition I/1.6.1) can be expressed in terms of expected values ($\rightarrow$ Proof I/1.6.3) as

$$\text{Var}(X) = \text{E}(X^2) - \text{E}(X)^2 \ . \tag{3}$$

The expected value of a gamma random variable ($\rightarrow$ Proof II/3.4.8) is

$$\text{E}(X) = \frac{a}{b} \ . \tag{4}$$

With the probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5), the expected value of a squared gamma random variable is

$$
\begin{aligned}
\text{E}(X^2) &= \int_0^\infty x^2 \cdot \frac{b^a}{\Gamma(a)} x^{a-1} \exp[-bx] \, \mathrm{d}x \\
&= \int_0^\infty \frac{b^a}{\Gamma(a)} x^{(a+2)-1} \exp[-bx] \, \mathrm{d}x \\
&= \int_0^\infty \frac{1}{b^2} \cdot \frac{b^{a+2}}{\Gamma(a)} x^{(a+2)-1} \exp[-bx] \, \mathrm{d}x \ .
\end{aligned}
\tag{5}
$$

Twice-applying the relation $\Gamma(x+1) = \Gamma(x) \cdot x$, we have

$$\text{E}(X^2) = \int_0^\infty \frac{a(a+1)}{b^2} \cdot \frac{b^{a+2}}{\Gamma(a+2)} x^{(a+2)-1} \exp[-bx] \, \mathrm{d}x \tag{6}$$

and again using the density of the gamma distribution ($\rightarrow$ Proof II/3.4.5), we get

$$
\begin{aligned}
\text{E}(X^2) &= \frac{a(a+1)}{b^2} \int_0^\infty \text{Gam}(x; a+2, b) \, \mathrm{d}x \\
&= \frac{a^2 + a}{b^2} \ .
\end{aligned}
\tag{7}
$$

Plugging (7) and (4) into (3), the variance of a gamma random variable finally becomes

$$
\begin{aligned}
\text{Var}(X) &= \frac{a^2 + a}{b^2} - \left(\frac{a}{b}\right)^2 \\
&= \frac{a}{b^2} \ .
\end{aligned}
\tag{8}
$$

3.4.10 Logarithmic expectation

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a gamma distribution ($\rightarrow$ Definition II/3.4.1):

$$X \sim \mathrm{Gam}(a, b) \, . \tag{1}$$

Then, the expectation ($\rightarrow$ Definition I/1.5.1) of the natural logarithm of X is

$$\mathrm{E}(\ln X) = \psi(a) - \ln(b) \tag{2}$$

where $\psi(x)$ is the digamma function.

Proof: Let $Y = \ln(X)$, such that $\mathrm{E}(Y) = \mathrm{E}(\ln X)$ and consider the special case that $b = 1$. In this case, the probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5) is

$$f_X(x) = \frac{1}{\Gamma(a)} \, x^{a-1} \exp[-x] \, . \tag{3}$$

Multiplying this function with $\mathrm{d}x$, we obtain

$$f_X(x) \, \mathrm{d}x = \frac{1}{\Gamma(a)} \, x^a \exp[-x] \, \frac{\mathrm{d}x}{x} \, . \tag{4}$$

Substituting $y = \ln x$, i.e. $x = e^y$, such that $\mathrm{d}x/\mathrm{d}y = x$, i.e. $\mathrm{d}x/x = \mathrm{d}y$, we get

$$
\begin{aligned}
f_Y(y) \, \mathrm{d}y &= \frac{1}{\Gamma(a)} \, (e^y)^a \exp[-e^y] \, \mathrm{d}y \\
&= \frac{1}{\Gamma(a)} \exp\left[ay - e^y\right] \mathrm{d}y \, .
\end{aligned}
\tag{5}
$$

Because $f_Y(y)$ integrates to one, we have

$$
\begin{aligned}
1 &= \int_{\mathbb{R}} f_Y(y) \, \mathrm{d}y \\
1 &= \int_{\mathbb{R}} \frac{1}{\Gamma(a)} \exp\left[ay - e^y\right] \mathrm{d}y \\
\Gamma(a) &= \int_{\mathbb{R}} \exp\left[ay - e^y\right] \mathrm{d}y \, .
\end{aligned}
\tag{6}
$$

Note that the integrand in (6) is differentiable with respect to a:

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}a} \exp\left[ay - e^y\right] \mathrm{d}y &= y \exp\left[ay - e^y\right] \mathrm{d}y \\
&\stackrel{(5)}{=} \Gamma(a) \, y \, f_Y(y) \, \mathrm{d}y \, .
\end{aligned}
\tag{7}
$$

Now we can calculate the expected value of $Y = \ln(X)$:

$$
\begin{aligned}
\mathrm{E}(Y) &= \int_{\mathbb{R}} y \, f_Y(y) \, \mathrm{d}y \\
&\overset{(7)}{=} \frac{1}{\Gamma(a)} \int_{\mathbb{R}} \frac{\mathrm{d}}{\mathrm{d}a} \exp\left[ay - e^y\right] \, \mathrm{d}y \\
&= \frac{1}{\Gamma(a)} \frac{\mathrm{d}}{\mathrm{d}a} \int_{\mathbb{R}} \exp\left[ay - e^y\right] \, \mathrm{d}y \\
&\overset{(6)}{=} \frac{1}{\Gamma(a)} \frac{\mathrm{d}}{\mathrm{d}a} \Gamma(a) \\
&= \frac{\Gamma'(a)}{\Gamma(a)} \ .
\end{aligned}
\tag{8}
$$

Using the derivative of a logarithmized function

$$
\frac{\mathrm{d}}{\mathrm{d}x} \ln f(x) = \frac{f'(x)}{f(x)}
\tag{9}
$$

and the definition of the digamma function

$$
\psi(x) = \frac{\mathrm{d}}{\mathrm{d}x} \ln \Gamma(x) \ ,
\tag{10}
$$

we have

$$
\mathrm{E}(Y) = \psi(a) \ .
\tag{11}
$$

Finally, noting that $1/b$ acts as a scaling parameter ($\rightarrow$ Proof II/3.4.3) on a gamma-distributed ($\rightarrow$ Definition II/3.4.1) random variable ($\rightarrow$ Definition I/1.1.3),

$$
X \sim \mathrm{Gam}(a, 1) \quad \Rightarrow \quad \frac{1}{b} X \sim \mathrm{Gam}(a, b) \ ,
\tag{12}
$$

and that a scaling parameter acts additively on the logarithmic expectation of a random variable,

$$
\mathrm{E}\left[\ln(cX)\right] = \mathrm{E}\left[\ln(X) + \ln(c)\right] = \mathrm{E}\left[\ln(X)\right] + \ln(c) \ ,
\tag{13}
$$

it follows that

$$
X \sim \mathrm{Gam}(a, b) \quad \Rightarrow \quad \mathrm{E}(\ln X) = \psi(a) - \ln(b) \ .
\tag{14}
$$

3.4.11   Expectation of x ln x

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a gamma distribution ($\rightarrow$ Definition II/3.4.1):

$$X \sim \mathrm{Gam}(a, b) \ . \tag{1}$$

Then, the mean or expected value ($\rightarrow$ Definition I/1.5.1) of $(X \cdot \ln X)$ is

$$\mathrm{E}(X \ln X) = \frac{a}{b} \left[\psi(a) - \ln(b) \right] \ . \tag{2}$$

Proof: With the definition of the expected value ($\rightarrow$ Definition I/1.5.1), the law of the unconscious statistician ($\rightarrow$ Proof I/1.5.9) and the probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5), we have:

$$
\begin{aligned}
\mathrm{E}(X \ln X) &= \int_0^\infty x \ln x \cdot \frac{b^a}{\Gamma(a)} x^{a-1} \exp[-bx] \, \mathrm{d}x \\
&= \frac{1}{\Gamma(a)} \int_0^\infty \ln x \cdot \frac{b^{a+1}}{b} x^a \exp[-bx] \, \mathrm{d}x \\
&= \frac{\Gamma(a+1)}{\Gamma(a) \, b} \int_0^\infty \ln x \cdot \frac{b^{a+1}}{\Gamma(a+1)} x^{(a+1)-1} \exp[-bx] \, \mathrm{d}x
\end{aligned}
\tag{3}
$$

The integral now corresponds to the logarithmic expectation of a gamma distribution ($\rightarrow$ Proof II/3.4.10) with shape $a+1$ and rate b

$$\mathrm{E}(\ln Y) \quad \text{where} \quad Y \sim \mathrm{Gam}(a+1, b) \tag{4}$$

which is given by ($\rightarrow$ Proof II/3.4.10)

$$\mathrm{E}(\ln Y) = \psi(a+1) - \ln(b) \tag{5}$$

where $\psi(x)$ is the digamma function. Additionally employing the relation

$$\Gamma(x+1) = \Gamma(x) \cdot x \quad \Leftrightarrow \quad \frac{\Gamma(x+1)}{\Gamma(x)} = x \ , \tag{6}$$

the expression in equation (3) develops into:

$$\mathrm{E}(X \ln X) = \frac{a}{b} \left[\psi(a) - \ln(b) \right] \ . \tag{7}$$

3.4.12 Kullback-Leibler divergence

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3). Assume two gamma distributions ($\rightarrow$ Definition II/3.4.1) P and Q specifying the probability distribution of X as

$$
\begin{aligned}
P &: \ X \sim \text{Gam}(a_1, b_1) \\
Q &: \ X \sim \text{Gam}(a_2, b_2) \ .
\end{aligned}
\tag{1}
$$

Then, the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) of P from Q is given by

$$
\text{KL}[P \,||\, Q] = a_2 \ln \frac{b_1}{b_2} - \ln \frac{\Gamma(a_1)}{\Gamma(a_2)} + (a_1 - a_2)\, \psi(a_1) - (b_1 - b_2) \frac{a_1}{b_1} \ .
\tag{2}
$$

Proof: The KL divergence for a continuous random variable ($\rightarrow$ Definition I/2.5.1) is given by

$$
\text{KL}[P \,||\, Q] = \int_{\mathcal{X}} p(x) \ln \frac{p(x)}{q(x)} \, \mathrm{d}x
\tag{3}
$$

which, applied to the gamma distributions ($\rightarrow$ Definition II/3.4.1) in (1), yields

$$
\begin{aligned}
\text{KL}[P \,||\, Q] &= \int_{-\infty}^{+\infty} \text{Gam}(x; a_1, b_1) \ln \frac{\text{Gam}(x; a_1, b_1)}{\text{Gam}(x; a_2, b_2)} \, \mathrm{d}x \\
&= \left\langle \ln \frac{\text{Gam}(x; a_1, b_1)}{\text{Gam}(x; a_2, b_2)} \right\rangle_{p(x)} .
\end{aligned}
\tag{4}
$$

Using the probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5), this becomes:

$$
\begin{aligned}
\text{KL}[P \,||\, Q] &= \left\langle \ln \frac{\frac{b_1{}^{a_1}}{\Gamma(a_1)} x^{a_1-1} \exp[-b_1 x]}{\frac{b_2{}^{a_2}}{\Gamma(a_2)} x^{a_2-1} \exp[-b_2 x]} \right\rangle_{p(x)} \\
&= \left\langle \ln \left(\frac{b_1{}^{a_1}}{b_2{}^{a_2}} \cdot \frac{\Gamma(a_2)}{\Gamma(a_1)} \cdot x^{a_1-a_2} \cdot \exp[-(b_1 - b_2)x] \right) \right\rangle_{p(x)} \\
&= \left\langle a_1 \cdot \ln b_1 - a_2 \cdot \ln b_2 - \ln \Gamma(a_1) + \ln \Gamma(a_2) + (a_1 - a_2) \cdot \ln x - (b_1 - b_2) \cdot x \right\rangle_{p(x)} .
\end{aligned}
\tag{5}
$$

Using the mean of the gamma distribution ($\rightarrow$ Proof II/3.4.8) and the expected value of a logarithmized gamma variate ($\rightarrow$ Proof II/3.4.10)

$$
\begin{aligned}
x \sim \text{Gam}(a, b) \quad &\Rightarrow \quad \langle x \rangle = \frac{a}{b} \quad \text{and} \\
&\quad\quad \langle \ln x \rangle = \psi(a) - \ln(b) \ ,
\end{aligned}
\tag{6}
$$

the Kullback-Leibler divergence from (5) becomes:

$$
\begin{aligned}
\text{KL}[P \,||\, Q] &= a_1 \cdot \ln b_1 - a_2 \cdot \ln b_2 - \ln \Gamma(a_1) + \ln \Gamma(a_2) + (a_1 - a_2) \cdot (\psi(a_1) - \ln(b_1)) - (b_1 - b_2) \cdot \frac{a_1}{b_1} \\
&= a_2 \cdot \ln b_1 - a_2 \cdot \ln b_2 - \ln \Gamma(a_1) + \ln \Gamma(a_2) + (a_1 - a_2) \cdot \psi(a_1) - (b_1 - b_2) \cdot \frac{a_1}{b_1} \ .
\end{aligned}
\tag{7}
$$

Finally, combining the logarithms, we get:

$$\mathrm{KL}[P \,\|\, Q] = a_2 \ln \frac{b_1}{b_2} - \ln \frac{\Gamma(a_1)}{\Gamma(a_2)} + (a_1 - a_2)\,\psi(a_1) - (b_1 - b_2)\,\frac{a_1}{b_1} \, . \tag{8}$$

3.5   Exponential distribution

3.5.1   Definition

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3). Then, X is said to be exponentially distributed with rate (or, inverse scale) λ

$$X \sim \mathrm{Exp}(\lambda) \, , \tag{1}$$

if and only if its probability density function ($\rightarrow$ Definition I/1.4.4) is given by

$$\mathrm{Exp}(x; \lambda) = \lambda \exp[-\lambda x], \quad x \geq 0 \tag{2}$$

where $\lambda > 0$, and the density is zero, if $x < 0$.

Sources:
- Wikipedia (2020): "Exponential distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-08; URL: https://en.wikipedia.org/wiki/Exponential_distribution#Definitions.

Metadata: ID: D8 | shortcut: exp | author: JoramSoch | date: 2020-02-08, 23:48.

3.5.2   Special case of gamma distribution

Theorem: The exponential distribution ($\rightarrow$ Definition II/3.5.1) is a special case of the gamma distribution ($\rightarrow$ Definition II/3.4.1) with shape $a = 1$ and rate $b = \lambda$.

Proof: The probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5) is

$$\mathrm{Gam}(x; a, b) = \frac{b^a}{\Gamma(a)} x^{a-1} \exp[-bx] \, . \tag{1}$$

Setting $a = 1$ and $b = \lambda$, we obtain

$$
\begin{aligned}
\mathrm{Gam}(x; 1, \lambda) &= \frac{\lambda^1}{\Gamma(1)} x^{1-1} \exp[-\lambda x] \\
&= \frac{x^0}{\Gamma(1)} \lambda \exp[-\lambda x] \\
&= \lambda \exp[-\lambda x]
\end{aligned}
\tag{2}
$$

which is equivalent to the probability density function of the exponential distribution ($\rightarrow$ Proof II/3.5.3).

Sources:
- original work

Metadata: ID: P69 | shortcut: exp-gam | author: JoramSoch | date: 2020-03-02, 20:49.

3.5.3 Probability density function

Theorem: Let X be a non-negative random variable ($\rightarrow$ Definition I/1.1.3) following an exponential distribution ($\rightarrow$ Definition II/3.5.1):

$$X \sim \mathrm{Exp}(\lambda) \,. \tag{1}$$

Then, the probability density function ($\rightarrow$ Definition I/1.4.4) of X is

$$f_X(x) = \lambda \exp[-\lambda x] \,. \tag{2}$$

Proof: This follows directly from the definition of the exponential distribution ($\rightarrow$ Definition II/3.5.1).

Sources:
- original work

Metadata: ID: P46 | shortcut: exp-pdf | author: JoramSoch | date: 2020-02-08, 23:53.

3.5.4 Cumulative distribution function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following an exponential distribution ($\rightarrow$ Definition II/3.5.1):

$$X \sim \mathrm{Exp}(\lambda) \,. \tag{1}$$

Then, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of X is

$$F_X(x) = \begin{cases} 0 \,, & \text{if } x < 0 \\ 1 - \exp[-\lambda x] \,, & \text{if } x \geq 0 \,. \end{cases} \tag{2}$$

Proof: The probability density function of the exponential distribution ($\rightarrow$ Proof II/3.5.3) is:

$$\mathrm{Exp}(x; \lambda) = \begin{cases} 0 \,, & \text{if } x < 0 \\ \lambda \exp[-\lambda x] \,, & \text{if } x \geq 0 \,. \end{cases} \tag{3}$$

Thus, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) is:

$$F_X(x) = \int_{-\infty}^{x} \mathrm{Exp}(z; \lambda) \, \mathrm{d}z \,. \tag{4}$$

If $x < 0$, we have:

$$F_X(x) = \int_{-\infty}^{x} 0 \, \mathrm{d}z = 0 \ . \tag{5}$$

If $x \geq 0$, we have using (3):

$$
\begin{aligned}
F_X(x) &= \int_{-\infty}^{0} \mathrm{Exp}(z; \lambda) \, \mathrm{d}z + \int_{0}^{x} \mathrm{Exp}(z; \lambda) \, \mathrm{d}z \\
&= \int_{-\infty}^{0} 0 \, \mathrm{d}z + \int_{0}^{x} \lambda \exp[-\lambda z] \, \mathrm{d}z \\
&= 0 + \lambda \left[-\frac{1}{\lambda} \exp[-\lambda z] \right]_{0}^{x} \\
&= \lambda \left[\left(-\frac{1}{\lambda} \exp[-\lambda x] \right) - \left(-\frac{1}{\lambda} \exp[-\lambda \cdot 0] \right) \right] \\
&= 1 - \exp[-\lambda x] \ .
\end{aligned}
\tag{6}
$$

3.5.5   Quantile function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following an exponential distribution ($\rightarrow$ Definition II/3.5.1):

$$X \sim \mathrm{Exp}(\lambda) \ . \tag{1}$$

Then, the quantile function ($\rightarrow$ Definition I/1.4.17) of X is

$$Q_X(p) = \begin{cases} -\infty \ , & \text{if } p = 0 \\ -\frac{\ln(1-p)}{\lambda} \ , & \text{if } p > 0 \ . \end{cases} \tag{2}$$

Proof: The cumulative distribution function of the exponential distribution ($\rightarrow$ Proof II/3.5.4) is:

$$F_X(x) = \begin{cases} 0 \ , & \text{if } x < 0 \\ 1 - \exp[-\lambda x] \ , & \text{if } x \geq 0 \ . \end{cases} \tag{3}$$

The quantile function $Q_X(p)$ is defined as ($\rightarrow$ Definition I/1.4.17) the smallest x, such that $F_X(x) = p$:

$$Q_X(p) = \min \{ x \in \mathbb{R} \mid F_X(x) = p \} \ . \tag{4}$$

Thus, we have $Q_X(p) = -\infty$, if $p = 0$. When $p > 0$, it holds that ($\rightarrow$ Proof I/1.4.18)

$$Q_X(p) = F_X^{-1}(x) \ . \tag{5}$$

This can be derived by rearranging equation (3):

$$
\begin{aligned}
p &= 1 - \exp[-\lambda x] \\
\exp[-\lambda x] &= 1 - p \\
-\lambda x &= \ln(1 - p) \\
x &= -\frac{\ln(1 - p)}{\lambda} \; .
\end{aligned}
\tag{6}
$$

- original work

Metadata: ID: P50 | shortcut: exp-qf | author: JoramSoch | date: 2020-02-12, 15:48.

3.5.6 Mean

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following an exponential distribution ($\rightarrow$ Definition II/3.5.1):

$$
X \sim \mathrm{Exp}(\lambda) \; .
\tag{1}
$$

Then, the mean or expected value ($\rightarrow$ Definition I/1.5.1) of X is

$$
\mathrm{E}(X) = \frac{1}{\lambda} \; .
\tag{2}
$$

Proof: The expected value ($\rightarrow$ Definition I/1.5.1) is the probability-weighted average over all possible values:

$$
\mathrm{E}(X) = \int_{\mathcal{X}} x \cdot f_X(x) \, \mathrm{d}x \; .
\tag{3}
$$

With the probability density function of the exponential distribution ($\rightarrow$ Proof II/3.5.3), this reads:

$$
\begin{aligned}
\mathrm{E}(X) &= \int_0^{+\infty} x \cdot \lambda \exp(-\lambda x) \, \mathrm{d}x \\
&= \lambda \int_0^{+\infty} x \cdot \exp(-\lambda x) \, \mathrm{d}x \; .
\end{aligned}
\tag{4}
$$

Using the following anti-deriative

$$
\int x \cdot \exp(-\lambda x) \, \mathrm{d}x = \left(-\frac{1}{\lambda} x - \frac{1}{\lambda^2} \right) \exp(-\lambda x) \; ,
\tag{5}
$$

the expected value becomes

$$\begin{aligned}
\mathrm{E}(X) &= \lambda \left[\left(-\frac{1}{\lambda}x - \frac{1}{\lambda^2} \right) \exp(-\lambda x) \right]_0^{+\infty} \\
&= \lambda \left[\lim_{x \to \infty} \left(-\frac{1}{\lambda}x - \frac{1}{\lambda^2} \right) \exp(-\lambda x) - \left(-\frac{1}{\lambda} \cdot 0 - \frac{1}{\lambda^2} \right) \exp(-\lambda \cdot 0) \right] \\
&= \lambda \left[0 + \frac{1}{\lambda^2} \right] \\
&= \frac{1}{\lambda} \, .
\end{aligned} \tag{6}$$

- Koch, Karl-Rudolf (2007): "Expected Value"; in: *Introduction to Bayesian Statistics*, Springer, Berlin/Heidelberg, 2007, p. 39, eq. 2.142a; URL: https://www.springer.com/de/book/9783540727231; DOI: 10.1007/978-3-540-72726-2.

Metadata: ID: P47 | shortcut: exp-mean | author: JoramSoch | date: 2020-02-10, 21:57.

3.5.7 Median

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following an exponential distribution ($\to$ Definition II/3.5.1):

$$X \sim \mathrm{Exp}(\lambda) \, . \tag{1}$$

Then, the median ($\to$ Definition I/1.9.1) of X is

$$\mathrm{median}(X) = \frac{\ln 2}{\lambda} \, . \tag{2}$$

Proof: The median ($\to$ Definition I/1.9.1) is the value at which the cumulative distribution function ($\to$ Definition I/1.4.8) is $1/2$:

$$F_X(\mathrm{median}(X)) = \frac{1}{2} \, . \tag{3}$$

The cumulative distribution function of the exponential distribution ($\to$ Proof II/3.5.4) is

$$F_X(x) = 1 - \exp[-\lambda x], \quad x \geq 0 \, . \tag{4}$$

Thus, the inverse CDF is

$$x = -\frac{\ln(1-p)}{\lambda} \tag{5}$$

and setting $p = 1/2$, we obtain:

$$\mathrm{median}(X) = -\frac{\ln(1 - \frac{1}{2})}{\lambda} = \frac{\ln 2}{\lambda} \, . \tag{6}$$

Sources:

- original work

Metadata: ID: P49 | shortcut: exp-med | author: JoramSoch | date: 2020-02-11, 15:03.

3.5.8 Mode

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following an exponential distribution ($\rightarrow$ Definition II/3.5.1):

$$X \sim \mathrm{Exp}(\lambda) \ . \tag{1}$$

Then, the mode ($\rightarrow$ Definition I/1.9.2) of X is

$$\mathrm{mode}(X) = 0 \ . \tag{2}$$

Proof: The mode ($\rightarrow$ Definition I/1.9.2) is the value which maximizes the probability density function ($\rightarrow$ Definition I/1.4.4):

$$\mathrm{mode}(X) = \arg\max_x f_X(x) \ . \tag{3}$$

The probability density function of the exponential distribution ($\rightarrow$ Proof II/3.5.3) is:

$$f_X(x) = \begin{cases} 0 \ , & \text{if } x < 0 \\ \lambda \exp[-\lambda x] \ , & \text{if } x \geq 0 \ . \end{cases} \tag{4}$$

Since

$$\lim_{x \to 0} f_X(x) = \infty \tag{5}$$

and

$$f_X(x) < \infty \quad \text{for any} \quad x \neq 0 \ , \tag{6}$$

it follows that

$$\mathrm{mode}(X) = 0 \ . \tag{7}$$

Sources:
- original work

3.6 Chi-square distribution

3.6.1 Definition

Definition: Let $X_1, ..., X_k$ be independent ($\rightarrow$ Definition I/1.2.6) random variables ($\rightarrow$ Definition I/1.1.3) where each of them is following a standard normal distribution ($\rightarrow$ Definition II/3.2.2):

$$X_i \sim \mathcal{N}(0,1) \quad \text{for} \quad i = 1, \ldots, n . \tag{1}$$

Then, the sum of their squares follows a chi-square distribution with k degrees of freedom:

$$Y = \sum_{i=1}^{k} X_i^2 \sim \chi^2(k) \quad \text{where} \quad k > 0 . \tag{2}$$

The probability density function of the chi-square distribution ($\rightarrow$ Proof II/3.6.3) with k degress of freedom is

$$\chi^2(x; k) = \frac{1}{2^{k/2}\Gamma(k/2)} \, x^{k/2-1} \, e^{-x/2} \tag{3}$$

where $k > 0$ and the density is zero if $x \leq 0$.

- Wikipedia (2020): "Chi-square distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-10-12; URL: https://en.wikipedia.org/wiki/Chi-square_distribution#Definitions.
- Robert V. Hogg, Joseph W. McKean, Allen T. Craig (2018): "The Chi-Squared-Distribution"; in: *Introduction to Mathematical Statistics*, Pearson, Boston, 2019, p. 178, eq. 3.3.7; URL: https://www.pearson.com/store/p/introduction-to-mathematical-statistics/P100000843744.

Metadata: ID: D100 | shortcut: chi2 | author: kjpetrykowski | date: 2020-10-13, 01:20.

3.6.2 Special case of gamma distribution

Theorem: The chi-square distribution ($\rightarrow$ Definition II/3.6.1) with k degrees of freedom is a special case of the gamma distribution ($\rightarrow$ Definition II/3.4.1) with shape $\frac{k}{2}$ and rate $\frac{1}{2}$:

$$X \sim \text{Gam}\left(\frac{k}{2}, \frac{1}{2}\right) \Rightarrow X \sim \chi^2(k) . \tag{1}$$

Proof: The probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5) for $x > 0$, where α is the shape parameter and β is the rate paramete, is as follows:

$$\text{Gam}(x; \alpha, \beta) = \frac{\beta^\alpha}{\Gamma(\alpha)} \, x^{\alpha-1} \, e^{-\beta x} \tag{2}$$

If we let $\alpha = k/2$ and $\beta = 1/2$, we obtain

$$\text{Gam}\left(x; \frac{k}{2}, \frac{1}{2}\right) = \frac{x^{k/2-1} \, e^{-x/2}}{\Gamma(k/2)2^{k/2}} = \frac{1}{2^{k/2}\Gamma(k/2)} \, x^{k/2-1} \, e^{-x/2} \tag{3}$$

which is equivalent to the probability density function of the chi-square distribution ($\rightarrow$ Proof II/3.6.3).

Sources:

- original work

Metadata: ID: P174 | shortcut: chi2-gam | author: kjpetrykowski | date: 2020-10-12, 22:15.

3.6.3   Probability density function

Theorem: Let Y be a random variable ($\to$ Definition I/1.1.3) following a chi-square distribution ($\to$ Definition II/3.6.1):

$$
Y \sim \chi^2(k) \ . \tag{1}
$$

Then, the probability density function ($\to$ Definition I/1.4.4) of Y is

$$
f_Y(y) = \frac{1}{2^{k/2}\,\Gamma(k/2)}\, y^{k/2-1}\, e^{-y/2} \ . \tag{2}
$$

Proof: A chi-square-distributed random variable ($\to$ Definition II/3.6.1) with k degrees of freedom is defined as the sum of k squared standard normal random variables ($\to$ Definition II/3.2.2):

$$
X_1,\ldots,X_k \sim \mathcal{N}(0,1) \quad \Rightarrow \quad Y = \sum_{i=1}^{k} X_i^2 \sim \chi^2(k) \ . \tag{3}
$$

Let $x_1,\ldots,x_k$ be values of $X_1,\ldots,X_k$ and consider $x = (x_1,\ldots,x_k)$ to be a point in k-dimensional space. Define

$$
y = \sum_{i=1}^{k} x_i^2 \tag{4}
$$

and let $f_Y(y)$ and $F_Y(y)$ be the probability density function ($\to$ Definition I/1.4.4) and cumulative distribution function ($\to$ Definition I/1.4.8) of Y. Because the PDF is the first derivative of the CDF ($\to$ Proof I/1.4.7), we can write:

$$
F_Y(y) = \frac{F_Y(y)}{\mathrm{d}y}\,\mathrm{d}y = f_Y(y)\,\mathrm{d}y \ . \tag{5}
$$

Then, the cumulative distribution function ($\to$ Definition I/1.4.8) of Y can be expressed as

$$
f_Y(y)\,\mathrm{d}y = \int_V \prod_{i=1}^{k} \left(\mathcal{N}(x_i;0,1)\,\mathrm{d}x_i \right) \tag{6}
$$

where $\mathcal{N}(x_i;0,1)$ is the probability density function ($\to$ Definition I/1.4.4) of the standard normal distribution ($\to$ Definition II/3.2.2) and V is the elemental shell volume at $y(x)$, which is proportional to the $(k-1)$-dimensional surface in k-space for which equation (4) is fulfilled. Using the probability density function of the normal distribution ($\to$ Proof II/3.2.7), equation (6) can be developed as follows:

$$f_Y(y)\,\mathrm{d}y = \int_V \prod_{i=1}^k \left(\frac{1}{\sqrt{2\pi}} \cdot \exp\left[-\frac{1}{2}x_i^2\right]\,\mathrm{d}x_i \right)$$

$$= \int_V \frac{\exp\left[-\frac{1}{2}\left(x_1^2 + \ldots + x_k^2\right)\right]}{(2\pi)^{k/2}}\,\mathrm{d}x_1 \ldots \mathrm{d}x_k \tag{7}$$

$$= \frac{1}{(2\pi)^{k/2}} \int_V \exp\left[-\frac{y}{2}\right]\,\mathrm{d}x_1 \ldots \mathrm{d}x_k \;.$$

Because y is constant within the set V, it can be moved out of the integral:

$$f_Y(y)\,\mathrm{d}y = \frac{\exp\left[-y/2\right]}{(2\pi)^{k/2}} \int_V \mathrm{d}x_1 \ldots \mathrm{d}x_k \;. \tag{8}$$

Now, the integral is simply the surface area of the $(k-1)$-dimensional sphere with radius $r = \sqrt{y}$, which is

$$A = 2r^{k-1}\frac{\pi^{k/2}}{\Gamma(k/2)} \;, \tag{9}$$

times the infinitesimal thickness of the sphere, which is

$$\frac{\mathrm{d}r}{\mathrm{d}y} = \frac{1}{2}y^{-1/2} \quad \Leftrightarrow \quad \mathrm{d}r = \frac{\mathrm{d}y}{2y^{1/2}} \;. \tag{10}$$

Substituting (9) and (10) into (8), we have:

$$f_Y(y)\,\mathrm{d}y = \frac{\exp\left[-y/2\right]}{(2\pi)^{k/2}} \cdot A\,\mathrm{d}r$$

$$= \frac{\exp\left[-y/2\right]}{(2\pi)^{k/2}} \cdot 2r^{k-1}\frac{\pi^{k/2}}{\Gamma(k/2)} \cdot \frac{\mathrm{d}y}{2y^{1/2}}$$

$$= \frac{1}{2^{k/2}\,\Gamma(k/2)} \cdot \frac{2\sqrt{y}^{\,k-1}}{2\sqrt{y}} \cdot \exp\left[-y/2\right]\,\mathrm{d}y \tag{11}$$

$$= \frac{1}{2^{k/2}\,\Gamma(k/2)} \cdot y^{\frac{k}{2}-1} \cdot \exp\left[-\frac{y}{2}\right]\,\mathrm{d}y \;.$$

From this, we get the final result in (2):

$$f_Y(y) = \frac{1}{2^{k/2}\,\Gamma(k/2)}\,y^{k/2-1}\,e^{-y/2} \;. \tag{12}$$

3.6.4 Moments

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a chi-square distribution ($\to$ Definition II/3.6.1):

$$X \sim \chi^2(k) \ . \tag{1}$$

If $m > -k/2$, then $E(X^m)$ exists and is equal to:

$$\mathrm{E}(X^m) = \frac{2^m \Gamma\left(\frac{k}{2} + m\right)}{\Gamma\left(\frac{k}{2}\right)} \ . \tag{2}$$

Proof: Combining the definition of the m-th raw moment ($\to$ Definition I/1.12.3) with the probability density function of the chi-square distribution ($\to$ Proof II/3.6.3), we have:

$$\mathrm{E}(X^m) = \int_0^\infty \frac{1}{\Gamma\left(\frac{k}{2}\right) 2^{k/2}} \, x^{(k/2)+m-1} \, e^{-x/2} \mathrm{d}x \ . \tag{3}$$

Now define a new variable $u = x/2$. As a result, we obtain:

$$\mathrm{E}(X^m) = \int_0^\infty \frac{1}{\Gamma\left(\frac{k}{2}\right) 2^{(k/2)-1}} \, 2^{(k/2)+m-1} \, u^{(k/2)+m-1} \, e^{-u} \mathrm{d}u \ . \tag{4}$$

This leads to the desired result when $m > -k/2$. Observe that, if m is a nonnegative integer, then $m > -k/2$ is always true. Therefore, all moments ($\to$ Definition I/1.12.1) of a chi-square distribution ($\to$ Definition II/3.6.1) exist and the m-th raw moment is given by the foregoing equation.

3.7 F-distribution

3.7.1 Definition

Definition: Let X_1 and X_2 be independent ($\to$ Definition I/1.2.6) random variables ($\to$ Definition I/1.1.3) following a chi-square distribution ($\to$ Definition II/3.6.1) with d_1 and d_2 degrees of freedom ($\to$ Definition "dof"), respectively:

$$\begin{aligned} X_1 &\sim \chi^2(d_1) \\ X_2 &\sim \chi^2(d_2) \ . \end{aligned} \tag{1}$$

Then, the ratio of X_1 to X_2, divided by their respective degrees of freedom, is said to be F-distributed with numerator degrees of freedom d_1 and denominator degrees of freedom d_2:

$$Y = \frac{X_1/d_1}{X_2/d_2} \sim F(d_1, d_2) \quad \text{where} \quad d_1, d_2 > 0 \ . \tag{2}$$

The *F*-distribution is also called "Snedecor's *F*-distribution" or "Fisher–Snedecor distribution", after Ronald A. Fisher and George W. Snedecor.

3.8 Beta distribution

3.8.1 Definition

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3). Then, X is said to follow a beta distribution with shape parameters α and β

$$X \sim \mathrm{Bet}(\alpha, \beta) \;, \tag{1}$$

if and only if its probability density function ($\rightarrow$ Definition I/1.4.4) is given by

$$\mathrm{Bet}(x; \alpha, \beta) = \frac{1}{\mathrm{B}(\alpha, \beta)} \, x^{\alpha-1} \, (1-x)^{\beta-1} \tag{2}$$

where $\alpha > 0$ and $\beta > 0$, and the density is zero, if $x \notin [0, 1]$.

Sources:
- Wikipedia (2020): "Beta distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-05-10; URL: https://en.wikipedia.org/wiki/Beta_distribution#Definitions.

Metadata: ID: D53 | shortcut: beta | author: JoramSoch | date: 2020-05-10, 20:29.

3.8.2 Probability density function

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a beta distribution ($\rightarrow$ Definition II/3.8.1):

$$X \sim \mathrm{Bet}(\alpha, \beta) \;. \tag{1}$$

Then, the probability density function ($\rightarrow$ Definition I/1.4.4) of X is

$$f_X(x) = \frac{1}{\mathrm{B}(\alpha, \beta)} \, x^{\alpha-1} \, (1-x)^{\beta-1} \;. \tag{2}$$

Proof: This follows directly from the definition of the beta distribution ($\rightarrow$ Definition II/3.8.1).

Sources:
- original work

Metadata: ID: P94 | shortcut: beta-pdf | author: JoramSoch | date: 2020-05-05, 21:03.

3.8.3 Moment-generating function

Theorem: Let X be a positive random variable ($\to$ Definition I/1.1.3) following a beta distribution ($\to$ Definition II/3.4.1):

$$X \sim \mathrm{Bet}(\alpha, \beta) . \tag{1}$$

Then, the moment-generating function ($\to$ Definition I/1.4.19) of X is

$$M_X(t) = 1 + \sum_{n=1}^{\infty} \left(\prod_{m=0}^{n-1} \frac{\alpha + m}{\alpha + \beta + m} \right) \frac{t^n}{n!} . \tag{2}$$

Proof: The probability density function of the beta distribution ($\to$ Proof II/3.8.2) is

$$f_X(x) = \frac{1}{\mathrm{B}(\alpha, \beta)} \, x^{\alpha-1} \, (1 - x)^{\beta-1} \tag{3}$$

and the moment-generating function ($\to$ Definition I/1.4.19) is defined as

$$M_X(t) = \mathrm{E} \left[e^{tX} \right] . \tag{4}$$

Using the expected value for continuous random variables ($\to$ Definition I/1.5.1), the moment-generating function of X therefore is

$$
\begin{aligned}
M_X(t) &= \int_0^1 \exp[tx] \cdot \frac{1}{\mathrm{B}(\alpha, \beta)} \, x^{\alpha-1} \, (1 - x)^{\beta-1} \, \mathrm{d}x \\
&= \frac{1}{\mathrm{B}(\alpha, \beta)} \int_0^1 e^{tx} \, x^{\alpha-1} \, (1 - x)^{\beta-1} \, \mathrm{d}x .
\end{aligned}
\tag{5}
$$

With the relationship between beta function and gamma function

$$\mathrm{B}(\alpha, \beta) = \frac{\Gamma(\alpha) \, \Gamma(\beta)}{\Gamma(\alpha + \beta)} \tag{6}$$

and the integral representation of the confluent hypergeometric function (Kummer's function of the first kind)

$$_1F_1(a, b, z) = \frac{\Gamma(b)}{\Gamma(a) \, \Gamma(b - a)} \int_0^1 e^{zu} \, u^{a-1} \, (1 - u)^{(b-a)-1} \, \mathrm{d}u , \tag{7}$$

the moment-generating function can be written as

$$M_X(t) = {}_1F_1(\alpha, \alpha + \beta, t) . \tag{8}$$

Note that the series equation for the confluent hypergeometric function (Kummer's function of the first kind) is

$$_1F_1(a, b, z) = \sum_{n=0}^{\infty} \frac{a^{\overline{n}}}{b^{\overline{n}}} \frac{z^n}{n!} \tag{9}$$

where $m^{\overline{n}}$ is the rising factorial

$$m^{\overline{n}} = \prod_{i=0}^{n-1} (m+i) \, , \tag{10}$$

so that the moment-generating function can be written as

$$M_X(t) = \sum_{n=0}^{\infty} \frac{\alpha^{\overline{n}}}{(\alpha+\beta)^{\overline{n}}} \frac{t^n}{n!} \, . \tag{11}$$

Applying the rising factorial equation (10) and using $m^{\overline{0}} = x^0 = 0! = 1$, we finally have:

$$M_X(t) = 1 + \sum_{n=1}^{\infty} \left(\prod_{m=0}^{n-1} \frac{\alpha+m}{\alpha+\beta+m} \right) \frac{t^n}{n!} \, . \tag{12}$$

Metadata: ID: P198 | shortcut: beta-mgf | author: JoramSoch | date: 2020-11-25, 06:55.

3.8.4   Cumulative distribution function

Theorem: Let X be a positive random variable ($\rightarrow$ Definition I/1.1.3) following a beta distribution ($\rightarrow$ Definition II/3.4.1):

$$X \sim \mathrm{Bet}(\alpha, \beta) \, . \tag{1}$$

Then, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of X is

$$F_X(x) = \frac{B(x; \alpha, \beta)}{B(\alpha, \beta)} \tag{2}$$

where $B(a, b)$ is the beta function and $B(x; a, b)$ is the incomplete gamma function.

Proof: The probability density function of the beta distribution ($\rightarrow$ Proof II/3.8.2) is:

$$f_X(x) = \frac{1}{\mathrm{B}(\alpha, \beta)} \, x^{\alpha-1} \, (1-x)^{\beta-1} \, . \tag{3}$$

Thus, the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) is:

$$\begin{aligned}
F_X(x) &= \int_0^x \mathrm{Bet}(z; \alpha, \beta) \, \mathrm{d}z \\
&= \int_0^x \frac{1}{\mathrm{B}(\alpha, \beta)} \, z^{\alpha-1} \, (1-z)^{\beta-1} \, \mathrm{d}z \\
&= \frac{1}{\mathrm{B}(\alpha, \beta)} \int_0^x z^{\alpha-1} \, (1-z)^{\beta-1} \, \mathrm{d}z \, .
\end{aligned} \tag{4}$$

With the definition of the incomplete beta function

$$B(x; a, b) = \int_0^x t^{a-1} (1-t)^{b-1} \, \mathrm{d}t \, , \tag{5}$$

we arrive at the final result given by equation (2):

$$F_X(x) = \frac{B(x; \alpha, \beta)}{B(\alpha, \beta)} \, . \tag{6}$$

3.8.5 Mean

Theorem: Let X be a random variable ($\rightarrow$ Definition I/1.1.3) following a beta distribution ($\rightarrow$ Definition II/3.8.1):

$$X \sim \mathrm{Bet}(\alpha, \beta) \, . \tag{1}$$

Then, the mean or expected value ($\rightarrow$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = \frac{\alpha}{\alpha + \beta} \, . \tag{2}$$

Proof: The expected value ($\rightarrow$ Definition I/1.5.1) is the probability-weighted average over all possible values:

$$\mathrm{E}(X) = \int_{\mathcal{X}} x \cdot f_X(x) \, \mathrm{d}x \, . \tag{3}$$

The probability density function of the beta distribution ($\rightarrow$ Proof II/3.8.2) is

$$f_X(x) = \frac{1}{\mathrm{B}(\alpha, \beta)} x^{\alpha-1} (1-x)^{\beta-1}, \quad 0 \le x \le 1 \tag{4}$$

where the beta function is given by a ratio gamma functions:

$$\mathrm{B}(\alpha, \beta) = \frac{\Gamma(\alpha) \cdot \Gamma(\beta)}{\Gamma(\alpha + \beta)} \, . \tag{5}$$

Combining (3), (4) and (5), we have:

$$\begin{aligned}
\mathrm{E}(X) &= \int_0^1 x \cdot \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha) \cdot \Gamma(\beta)} x^{\alpha-1} (1-x)^{\beta-1} \, \mathrm{d}x \\
&= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)} \cdot \frac{\Gamma(\alpha + 1)}{\Gamma(\alpha + 1 + \beta)} \int_0^1 \frac{\Gamma(\alpha + 1 + \beta)}{\Gamma(\alpha + 1) \cdot \Gamma(\beta)} x^{(\alpha+1)-1} (1-x)^{\beta-1} \, \mathrm{d}x \, .
\end{aligned} \tag{6}$$

Employing the relation $\Gamma(x+1) = \Gamma(x) \cdot x$, we have

$$
\begin{aligned}
\mathrm{E}(X) &= \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)} \cdot \frac{\alpha \cdot \Gamma(\alpha)}{(\alpha+\beta) \cdot \Gamma(\alpha+\beta)} \int_0^1 \frac{\Gamma(\alpha+1+\beta)}{\Gamma(\alpha+1) \cdot \Gamma(\beta)} \, x^{(\alpha+1)-1} \, (1-x)^{\beta-1} \, \mathrm{d}x \\
&= \frac{\alpha}{\alpha+\beta} \int_0^1 \frac{\Gamma(\alpha+1+\beta)}{\Gamma(\alpha+1) \cdot \Gamma(\beta)} \, x^{(\alpha+1)-1} \, (1-x)^{\beta-1} \, \mathrm{d}x
\end{aligned}
\tag{7}
$$

and again using the density of the beta distribution ($\to$ Proof II/3.8.2), we get

$$
\begin{aligned}
\mathrm{E}(X) &= \frac{\alpha}{\alpha+\beta} \int_0^1 \mathrm{Bet}(x; \alpha+1, \beta) \, \mathrm{d}x \\
&= \frac{\alpha}{\alpha+\beta} \; .
\end{aligned}
\tag{8}
$$

Sources:
- Boer Commander (2020): "Beta Distribution Mean and Variance Proof"; in: *YouTube*, retrieved on 2021-04-29; URL: https://www.youtube.com/watch?v=3OgCcnpZtZ8.

3.8.6   Variance

Theorem: Let X be a random variable ($\to$ Definition I/1.1.3) following a beta distribution ($\to$ Definition II/3.8.1):

$$
X \sim \mathrm{Bet}(\alpha, \beta) \; .
\tag{1}
$$

Then, the variance ($\to$ Definition I/1.6.1) of X is

$$
\mathrm{Var}(X) = \frac{\alpha\beta}{(\alpha+\beta+1) \cdot (\alpha+\beta)^2} \; .
\tag{2}
$$

Proof: The variance ($\to$ Definition I/1.6.1) can be expressed in terms of expected values ($\to$ Proof I/1.6.3) as

$$
\mathrm{Var}(X) = \mathrm{E}(X^2) - \mathrm{E}(X)^2 \; .
\tag{3}
$$

The expected value of a beta random variable ($\to$ Proof II/3.8.5) is

$$
\mathrm{E}(X) = \frac{\alpha}{\alpha+\beta} \; .
\tag{4}
$$

The probability density function of the beta distribution ($\to$ Proof II/3.8.2) is

$$
f_X(x) = \frac{1}{\mathrm{B}(\alpha, \beta)} \, x^{\alpha-1} \, (1-x)^{\beta-1}, \quad 0 \le x \le 1
\tag{5}
$$

where the beta function is given by a ratio gamma functions:

$$B(\alpha, \beta) = \frac{\Gamma(\alpha) \cdot \Gamma(\beta)}{\Gamma(\alpha + \beta)} \; . \tag{6}$$

Therefore, the expected value of a squared beta random variable becomes

$$
\begin{aligned}
E(X^2) &= \int_0^1 x^2 \cdot \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha) \cdot \Gamma(\beta)} \, x^{\alpha - 1} \, (1 - x)^{\beta - 1} \, \mathrm{d}x \\
&= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)} \cdot \frac{\Gamma(\alpha + 2)}{\Gamma(\alpha + 2 + \beta)} \int_0^1 \frac{\Gamma(\alpha + 2 + \beta)}{\Gamma(\alpha + 2) \cdot \Gamma(\beta)} \, x^{(\alpha + 2) - 1} \, (1 - x)^{\beta - 1} \, \mathrm{d}x \; .
\end{aligned}
\tag{7}
$$

Twice-applying the relation $\Gamma(x + 1) = \Gamma(x) \cdot x$, we have

$$
\begin{aligned}
E(X^2) &= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)} \cdot \frac{(\alpha + 1) \cdot \alpha \cdot \Gamma(\alpha)}{(\alpha + \beta + 1) \cdot (\alpha + \beta) \cdot \Gamma(\alpha + \beta)} \int_0^1 \frac{\Gamma(\alpha + 2 + \beta)}{\Gamma(\alpha + 2) \cdot \Gamma(\beta)} \, x^{(\alpha + 2) - 1} \, (1 - x)^{\beta - 1} \, \mathrm{d}x \\
&= \frac{(\alpha + 1) \cdot \alpha}{(\alpha + \beta + 1) \cdot (\alpha + \beta)} \int_0^1 \frac{\Gamma(\alpha + 2 + \beta)}{\Gamma(\alpha + 2) \cdot \Gamma(\beta)} \, x^{(\alpha + 2) - 1} \, (1 - x)^{\beta - 1} \, \mathrm{d}x
\end{aligned}
\tag{8}
$$

and again using the density of the beta distribution ($\to$ Proof II/3.8.2), we get

$$
\begin{aligned}
E(X^2) &= \frac{(\alpha + 1) \cdot \alpha}{(\alpha + \beta + 1) \cdot (\alpha + \beta)} \int_0^1 \mathrm{Bet}(x; \alpha + 2, \beta) \, \mathrm{d}x \\
&= \frac{(\alpha + 1) \cdot \alpha}{(\alpha + \beta + 1) \cdot (\alpha + \beta)} \; .
\end{aligned}
\tag{9}
$$

Plugging (9) and (4) into (3), the variance of a beta random variable finally becomes

$$
\begin{aligned}
\mathrm{Var}(X) &= \frac{(\alpha + 1) \cdot \alpha}{(\alpha + \beta + 1) \cdot (\alpha + \beta)} - \left(\frac{\alpha}{\alpha + \beta} \right)^2 \\
&= \frac{(\alpha^2 + \alpha) \cdot (\alpha + \beta)}{(\alpha + \beta + 1) \cdot (\alpha + \beta)^2} - \frac{\alpha^2 \cdot (\alpha + \beta + 1)}{(\alpha + \beta + 1) \cdot (\alpha + \beta)^2} \\
&= \frac{(\alpha^3 + \alpha^2 \beta + \alpha^2 + \alpha\beta) - (\alpha^3 + \alpha^2 \beta + \alpha^2)}{(\alpha + \beta + 1) \cdot (\alpha + \beta)^2} \\
&= \frac{\alpha\beta}{(\alpha + \beta + 1) \cdot (\alpha + \beta)^2} \; .
\end{aligned}
\tag{10}
$$

3.9   Wald distribution

3.9.1   Definition

Definition: Let X be a random variable ($\rightarrow$ Definition I/1.1.3). Then, X is said to follow a Wald distribution with drift rate γ and threshold α

$$X \sim \mathrm{Wald}(\gamma, \alpha) \;, \tag{1}$$

if and only if its probability density function ($\rightarrow$ Definition I/1.4.4) is given by

$$\mathrm{Wald}(x; \gamma, \alpha) = \frac{\alpha}{\sqrt{2\pi x^3}} \exp\left(-\frac{(\alpha - \gamma x)^2}{2x}\right) \tag{2}$$

where $\gamma > 0$, $\alpha > 0$, and the density is zero if $x \leq 0$.

Metadata: ID: D95 | shortcut: wald | author: tomfaulkenberry | date: 2020-09-04, 12:00.

3.9.2   Probability density function

Theorem: Let X be a positive random variable ($\rightarrow$ Definition I/1.1.3) following a Wald distribution ($\rightarrow$ Definition II/3.9.1):

$$X \sim \mathrm{Wald}(\gamma, \alpha) \;. \tag{1}$$

Then, the probability density function ($\rightarrow$ Definition I/1.4.4) of X is

$$f_X(x) = \frac{\alpha}{\sqrt{2\pi x^3}} \exp\left(-\frac{(\alpha - \gamma x)^2}{2x}\right) \;. \tag{2}$$

Proof: This follows directly from the definition of the Wald distribution ($\rightarrow$ Definition II/3.9.1).

Sources:
- original work

Metadata: ID: P162 | shortcut: wald-pdf | author: tomfaulkenberry | date: 2020-09-04, 12:00.

3.9.3   Moment-generating function

Theorem: Let X be a positive random variable ($\rightarrow$ Definition I/1.1.3) following a Wald distribution ($\rightarrow$ Definition II/3.9.1):

$$X \sim \mathrm{Wald}(\gamma, \alpha) \;. \tag{1}$$

Then, the moment-generating function ($\rightarrow$ Definition I/1.4.19) of X is

$$M_X(t) = \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right] . \tag{2}$$

Proof: The probability density function of the Wald distribution ($\to$ Proof II/3.9.2) is

$$f_X(x) = \frac{\alpha}{\sqrt{2\pi x^3}} \exp\left(-\frac{(\alpha - \gamma x)^2}{2x}\right) \tag{3}$$

and the moment-generating function ($\to$ Definition I/1.4.19) is defined as

$$M_X(t) = \mathrm{E}\left[e^{tX}\right] . \tag{4}$$

Using the definition of expected value for continuous random variables ($\to$ Definition I/1.5.1), the moment-generating function of X therefore is

$$
\begin{aligned}
M_X(t) &= \int_0^\infty e^{tx} \cdot \frac{\alpha}{\sqrt{2\pi x^3}} \cdot \exp\left[-\frac{(\alpha - \gamma x)^2}{2x}\right] dx \\
&= \frac{\alpha}{\sqrt{2\pi}} \int_0^\infty x^{-3/2} \cdot \exp\left[tx - \frac{(\alpha - \gamma x)^2}{2x}\right] dx .
\end{aligned}
\tag{5}
$$

To evaluate this integral, we will need two identities about modified Bessel functions of the second kind[1], denoted K_p. The function K_p (for $p \in \mathbb{R}$) is one of the two linearly independent solutions of the differential equation

$$x^2 \frac{d^2 y}{dx^2} + x\frac{dy}{dx} - (x^2 + p^2)y = 0 . \tag{6}$$

The first of these identities[2] gives an explicit solution for $K_{-1/2}$:

$$K_{-1/2}(x) = \sqrt{\frac{\pi}{2x}} e^{-x} . \tag{7}$$

The second of these identities[3] gives an integral representation of K_p:

$$K_p(\sqrt{ab}) = \frac{1}{2}\left(\frac{a}{b}\right)^{p/2} \int_0^\infty x^{p-1} \cdot \exp\left[-\frac{1}{2}\left(ax + \frac{b}{x}\right)\right] dx . \tag{8}$$

Starting from (5), we can expand the binomial term and rearrange the moment generating function into the following form:

$$
\begin{aligned}
M_X(t) &= \frac{\alpha}{\sqrt{2\pi}} \int_0^\infty x^{-3/2} \cdot \exp\left[tx - \frac{\alpha^2}{2x} + \alpha\gamma - \frac{\gamma^2 x}{2}\right] dx \\
&= \frac{\alpha}{\sqrt{2\pi}} \cdot e^{\alpha\gamma} \int_0^\infty x^{-3/2} \cdot \exp\left[\left(t - \frac{\gamma^2}{2}\right)x - \frac{\alpha^2}{2x}\right] dx \\
&= \frac{\alpha}{\sqrt{2\pi}} \cdot e^{\alpha\gamma} \int_0^\infty x^{-3/2} \cdot \exp\left[-\frac{1}{2}\left(\gamma^2 - 2t\right)x - \frac{1}{2} \cdot \frac{\alpha^2}{x}\right] dx .
\end{aligned}
\tag{9}
$$

---

[1] https://dlmf.nist.gov/10.25
[2] https://dlmf.nist.gov/10.39.2
[3] https://dlmf.nist.gov/10.32.10

The integral now has the form of the integral in (8) with $p = -1/2$, $a = \gamma^2 - 2t$, and $b = \alpha^2$. This allows us to write the moment-generating function in terms of the modified Bessel function $K_{-1/2}$:

$$M_X(t) = \frac{\alpha}{\sqrt{2\pi}} \cdot e^{\alpha\gamma} \cdot 2 \left(\frac{\gamma^2 - 2t}{\alpha^2} \right)^{1/4} \cdot K_{-1/2}\left(\sqrt{\alpha^2(\gamma^2 - 2t)} \right). \tag{10}$$

Combining with (7) and simplifying gives

$$
\begin{aligned}
M_X(t) &= \frac{\alpha}{\sqrt{2\pi}} \cdot e^{\alpha\gamma} \cdot 2 \left(\frac{\gamma^2 - 2t}{\alpha^2} \right)^{1/4} \cdot \sqrt{\frac{\pi}{2\sqrt{\alpha^2(\gamma^2 - 2t)}}} \cdot \exp\left[-\sqrt{\alpha^2(\gamma^2 - 2t)} \right] \\
&= \frac{\alpha}{\sqrt{2} \cdot \sqrt{\pi}} \cdot e^{\alpha\gamma} \cdot 2 \cdot \frac{(\gamma^2 - 2t)^{1/4}}{\sqrt{\alpha}} \cdot \frac{\sqrt{\pi}}{\sqrt{2} \cdot \sqrt{\alpha} \cdot (\gamma^2 - 2t)^{1/4}} \cdot \exp\left[-\sqrt{\alpha^2(\gamma^2 - 2t)} \right] \\
&= e^{\alpha\gamma} \cdot \exp\left[-\sqrt{\alpha^2(\gamma^2 - 2t)} \right] \\
&= \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)} \right].
\end{aligned}
\tag{11}
$$

This finishes the proof of (2).

3.9.4   Mean

Theorem: Let X be a positive random variable ($\rightarrow$ Definition I/1.1.3) following a Wald distribution ($\rightarrow$ Definition II/3.9.1):

$$X \sim \mathrm{Wald}(\gamma, \alpha). \tag{1}$$

Then, the mean or expected value ($\rightarrow$ Definition I/1.5.1) of X is

$$\mathrm{E}(X) = \frac{\alpha}{\gamma}. \tag{2}$$

Proof: The mean or expected value $\mathrm{E}(X)$ is the first moment ($\rightarrow$ Definition I/1.12.1) of X, so we can use ($\rightarrow$ Proof I/1.12.2) the moment-generating function of the Wald distribution ($\rightarrow$ Proof II/3.9.3) to calculate

$$\mathrm{E}(X) = M_X'(0). \tag{3}$$

First we differentiate

$$M_X(t) = \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)} \right] \tag{4}$$

with respect to t. Using the chain rule gives

$$
\begin{aligned}
M_X'(t) &= \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right] \cdot -\frac{1}{2}\left(\alpha^2(\gamma^2 - 2t)\right)^{-1/2} \cdot -2\alpha^2 \\
&= \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right] \cdot \frac{\alpha^2}{\sqrt{\alpha^2(\gamma^2 - 2t)}} \; .
\end{aligned}
\tag{5}
$$

Evaluating (5) at $t = 0$ gives the desired result:

$$
\begin{aligned}
M_X'(0) &= \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2(0))}\right] \cdot \frac{\alpha^2}{\sqrt{\alpha^2(\gamma^2 - 2(0))}} \\
&= \exp\left[\alpha\gamma - \sqrt{\alpha^2 \cdot \gamma^2}\right] \cdot \frac{\alpha^2}{\sqrt{\alpha^2 \cdot \gamma^2}} \\
&= \exp[0] \cdot \frac{\alpha^2}{\alpha\gamma} \\
&= \frac{\alpha}{\gamma} \; .
\end{aligned}
\tag{6}
$$

3.9.5 Variance

Theorem: Let X be a positive random variable ($\rightarrow$ Definition I/1.1.3) following a Wald distribution ($\rightarrow$ Definition II/3.9.1):

$$
X \sim \text{Wald}(\gamma, \alpha) \; .
\tag{1}
$$

Then, the variance ($\rightarrow$ Definition I/1.6.1) of X is

$$
\text{Var}(X) = \frac{\alpha}{\gamma^3} \; .
\tag{2}
$$

Proof: To compute the variance of X, we partition the variance into expected values ($\rightarrow$ Proof I/1.6.3):

$$
\text{Var}(X) = \text{E}(X^2) - \text{E}(X)^2.
\tag{3}
$$

We then use the moment-generating function of the Wald distribution ($\rightarrow$ Proof II/3.9.3) to calculate

$$
\text{E}(X^2) = M_X''(0) \; .
\tag{4}
$$

First we differentiate

$$
M_X(t) = \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right]
\tag{5}
$$

with respect to t. Using the chain rule gives

$$
\begin{aligned}
M_X'(t) &= \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right] \cdot -\frac{1}{2}\left(\alpha^2(\gamma^2 - 2t)\right)^{-1/2} \cdot -2\alpha^2 \\
&= \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right] \cdot \frac{\alpha^2}{\sqrt{\alpha^2(\gamma^2 - 2t)}} \\
&= \alpha \cdot \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right] \cdot (\gamma^2 - 2t)^{-1/2} \ .
\end{aligned}
\tag{6}
$$

Now we use the product rule to obtain the second derivative:

$$
\begin{aligned}
M_X''(t) &= \alpha \cdot \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right] \cdot (\gamma^2 - 2t)^{-1/2} \cdot -\frac{1}{2}\left(\alpha^2(\gamma^2 - 2t)\right)^{-1/2} \cdot -2\alpha^2 \\
&\quad + \alpha \cdot \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right] \cdot -\frac{1}{2}(\gamma^2 - 2t)^{-3/2} \cdot -2 \\
&= \alpha^2 \cdot \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right] \cdot (\gamma^2 - 2t)^{-1} \\
&\quad + \alpha \cdot \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right] \cdot (\gamma^2 - 2t)^{-3/2} \\
&= \alpha \cdot \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2t)}\right]\left[\frac{\alpha}{\gamma^2 - 2t} + \frac{1}{\sqrt{(\gamma^2 - 2t)^3}}\right] \ .
\end{aligned}
\tag{7}
$$

Applying (4) yields

$$
\begin{aligned}
\mathrm{E}(X^2) &= M_X''(0) \\
&= \alpha \cdot \exp\left[\alpha\gamma - \sqrt{\alpha^2(\gamma^2 - 2(0))}\right]\left[\frac{\alpha}{\gamma^2 - 2(0)} + \frac{1}{\sqrt{(\gamma^2 - 2(0))^3}}\right] \\
&= \alpha \cdot \exp\left[\alpha\gamma - \alpha\gamma\right] \cdot \left[\frac{\alpha}{\gamma^2} + \frac{1}{\gamma^3}\right] \\
&= \frac{\alpha^2}{\gamma^2} + \frac{\alpha}{\gamma^3} \ .
\end{aligned}
\tag{8}
$$

Since the mean of a Wald distribution ($\rightarrow$ Proof II/3.9.4) is given by $\mathrm{E}(X) = \alpha/\gamma$, we can apply (3) to show

$$
\begin{aligned}
\mathrm{Var}(X) &= \mathrm{E}(X^2) - \mathrm{E}(X)^2 \\
&= \frac{\alpha^2}{\gamma^2} + \frac{\alpha}{\gamma^3} - \left(\frac{\alpha}{\gamma}\right)^2 \\
&= \frac{\alpha}{\gamma^3}
\end{aligned}
\tag{9}
$$

which completes the proof of (2).

4 Multivariate continuous distributions

4.1 Multivariate normal distribution

4.1.1 Definition

Definition: Let X be an $n \times 1$ random vector ($\rightarrow$ Definition I/1.1.4). Then, X is said to be multivariate normally distributed with mean μ and covariance Σ

$$X \sim \mathcal{N}(\mu, \Sigma) \,, \tag{1}$$

if and only if its probability density function ($\rightarrow$ Definition I/1.4.4) is given by

$$\mathcal{N}(x; \mu, \Sigma) = \frac{1}{\sqrt{(2\pi)^n |\Sigma|}} \cdot \exp\left[-\frac{1}{2}(x - \mu)^{\mathrm{T}} \Sigma^{-1}(x - \mu) \right] \tag{2}$$

where μ is an $n \times 1$ real vector and Σ is an $n \times n$ positive definite matrix.

4.1.2 Probability density function

Theorem: Let X be a random vector ($\rightarrow$ Definition I/1.1.4) following a multivariate normal distribution ($\rightarrow$ Definition II/4.1.1):

$$X \sim \mathcal{N}(\mu, \Sigma) \,. \tag{1}$$

Then, the probability density function ($\rightarrow$ Definition I/1.4.4) of X is

$$f_X(x) = \frac{1}{\sqrt{(2\pi)^n |\Sigma|}} \cdot \exp\left[-\frac{1}{2}(x - \mu)^{\mathrm{T}} \Sigma^{-1}(x - \mu) \right] \,. \tag{2}$$

Proof: This follows directly from the definition of the multivariate normal distribution ($\rightarrow$ Definition II/4.1.1).

4.1.3 Differential entropy

Theorem: Let x follow a multivariate normal distribution ($\rightarrow$ Definition II/4.1.1)

$$x \sim \mathcal{N}(\mu, \Sigma) \,. \tag{1}$$

Then, the differential entropy ($\to$ Definition I/2.2.1) of x in nats is

$$h(x) = \frac{n}{2} \ln(2\pi) + \frac{1}{2} \ln |\Sigma| + \frac{1}{2} n \ . \tag{2}$$

Proof: The differential entropy ($\to$ Definition I/2.2.1) of a random variable is defined as

$$h(X) = - \int_{\mathcal{X}} p(x) \log_b p(x) \, \mathrm{d}x \ . \tag{3}$$

To measure $h(X)$ in nats, we set $b = e$, such that ($\to$ Definition I/1.5.1)

$$h(X) = -\mathrm{E}\left[\ln p(x)\right] \ . \tag{4}$$

With the probability density function of the multivariate normal distribution ($\to$ Proof II/4.1.2), the differential entropy of x is:

$$
\begin{aligned}
h(x) &= -\mathrm{E}\left[\ln\left(\frac{1}{\sqrt{(2\pi)^n |\Sigma|}} \cdot \exp\left[-\frac{1}{2}(x-\mu)^\mathrm{T}\Sigma^{-1}(x-\mu)\right]\right)\right] \\
&= -\mathrm{E}\left[-\frac{n}{2}\ln(2\pi) - \frac{1}{2}\ln|\Sigma| - \frac{1}{2}(x-\mu)^\mathrm{T}\Sigma^{-1}(x-\mu)\right] \\
&= \frac{n}{2}\ln(2\pi) + \frac{1}{2}\ln|\Sigma| + \frac{1}{2}\mathrm{E}\left[(x-\mu)^\mathrm{T}\Sigma^{-1}(x-\mu)\right] \ .
\end{aligned}
\tag{5}
$$

The last term can be evaluted as

$$
\begin{aligned}
\mathrm{E}\left[(x-\mu)^\mathrm{T}\Sigma^{-1}(x-\mu)\right] &= \mathrm{E}\left[\mathrm{tr}\left((x-\mu)^\mathrm{T}\Sigma^{-1}(x-\mu)\right)\right] \\
&= \mathrm{E}\left[\mathrm{tr}\left(\Sigma^{-1}(x-\mu)(x-\mu)^\mathrm{T}\right)\right] \\
&= \mathrm{tr}\left(\Sigma^{-1}\mathrm{E}\left[(x-\mu)(x-\mu)^\mathrm{T}\right]\right) \\
&= \mathrm{tr}\left(\Sigma^{-1}\Sigma\right) \\
&= \mathrm{tr}\left(I_n\right) \\
&= n \ ,
\end{aligned}
\tag{6}
$$

such that the differential entropy is

$$h(x) = \frac{n}{2} \ln(2\pi) + \frac{1}{2} \ln |\Sigma| + \frac{1}{2} n \ . \tag{7}$$

4.1.4 Kullback-Leibler divergence

Theorem: Let x be an $n \times 1$ random vector ($\to$ Definition I/1.1.4). Assume two multivariate normal distributions ($\to$ Definition II/4.1.1) P and Q specifying the probability distribution of x as

$$
\begin{aligned}
P &: \ x \sim \mathcal{N}(\mu_1, \Sigma_1) \\
Q &: \ x \sim \mathcal{N}(\mu_2, \Sigma_2) \ .
\end{aligned}
\tag{1}
$$

Then, the Kullback-Leibler divergence ($\to$ Definition I/2.5.1) of P from Q is given by

$$
\mathrm{KL}[P \,||\, Q] = \frac{1}{2} \left[(\mu_2 - \mu_1)^T \Sigma_2^{-1} (\mu_2 - \mu_1) + \mathrm{tr}(\Sigma_2^{-1} \Sigma_1) - \ln \frac{|\Sigma_1|}{|\Sigma_2|} - n \right] \ .
\tag{2}
$$

Proof: The KL divergence for a continuous random variable ($\to$ Definition I/2.5.1) is given by

$$
\mathrm{KL}[P \,||\, Q] = \int_{\mathcal{X}} p(x) \, \ln \frac{p(x)}{q(x)} \, \mathrm{d}x
\tag{3}
$$

which, applied to the multivariate normal distributions ($\to$ Definition II/4.1.1) in (1), yields

$$
\begin{aligned}
\mathrm{KL}[P \,||\, Q] &= \int_{\mathbb{R}^n} \mathcal{N}(x; \mu_1, \Sigma_1) \, \ln \frac{\mathcal{N}(x; \mu_1, \Sigma_1)}{\mathcal{N}(x; \mu_2, \Sigma_2)} \, \mathrm{d}x \\
&= \left\langle \ln \frac{\mathcal{N}(x; \mu_1, \Sigma_1)}{\mathcal{N}(x; \mu_2, \Sigma_2)} \right\rangle_{p(x)} \ .
\end{aligned}
\tag{4}
$$

Using the probability density function of the multivariate normal distribution ($\to$ Proof II/4.1.2), this becomes:

$$
\begin{aligned}
\mathrm{KL}[P \,||\, Q] &= \left\langle \ln \frac{\frac{1}{\sqrt{(2\pi)^n |\Sigma_1|}} \cdot \exp\left[-\frac{1}{2}(x - \mu_1)^{\mathrm{T}} \Sigma_1^{-1} (x - \mu_1) \right]}{\frac{1}{\sqrt{(2\pi)^n |\Sigma_2|}} \cdot \exp\left[-\frac{1}{2}(x - \mu_2)^{\mathrm{T}} \Sigma_2^{-1} (x - \mu_2) \right]} \right\rangle_{p(x)} \\
&= \left\langle \frac{1}{2} \ln \frac{|\Sigma_2|}{|\Sigma_1|} - \frac{1}{2}(x - \mu_1)^{\mathrm{T}} \Sigma_1^{-1} (x - \mu_1) + \frac{1}{2}(x - \mu_2)^{\mathrm{T}} \Sigma_2^{-1} (x - \mu_2) \right\rangle_{p(x)} \\
&= \frac{1}{2} \left\langle \ln \frac{|\Sigma_2|}{|\Sigma_1|} - (x - \mu_1)^{\mathrm{T}} \Sigma_1^{-1} (x - \mu_1) + (x - \mu_2)^{\mathrm{T}} \Sigma_2^{-1} (x - \mu_2) \right\rangle_{p(x)} \ .
\end{aligned}
\tag{5}
$$

Now, using the fact that $x = \mathrm{tr}(x)$, if a is scalar, and the trace property $\mathrm{tr}(ABC) = \mathrm{tr}(BCA)$, we have:

$$
\begin{aligned}
\mathrm{KL}[P \,||\, Q] &= \frac{1}{2} \left\langle \ln \frac{|\Sigma_2|}{|\Sigma_1|} - \mathrm{tr}\left[\Sigma_1^{-1}(x - \mu_1)(x - \mu_1)^{\mathrm{T}} \right] + \mathrm{tr}\left[\Sigma_2^{-1}(x - \mu_2)(x - \mu_2)^{\mathrm{T}} \right] \right\rangle_{p(x)} \\
&= \frac{1}{2} \left\langle \ln \frac{|\Sigma_2|}{|\Sigma_1|} - \mathrm{tr}\left[\Sigma_1^{-1}(x - \mu_1)(x - \mu_1)^{\mathrm{T}} \right] + \mathrm{tr}\left[\Sigma_2^{-1} \left(xx^{\mathrm{T}} - 2\mu_2 x^{\mathrm{T}} + \mu_2 \mu_2^{\mathrm{T}} \right) \right] \right\rangle_{p(x)} \ .
\end{aligned}
\tag{6}
$$

Because trace function and expected value ($\to$ Definition I/1.5.1) are both linear operators, the expectation can be moved inside the trace:

$$
\begin{aligned}
\mathrm{KL}[P \,||\, Q] &= \frac{1}{2} \left(\ln \frac{|\Sigma_2|}{|\Sigma_1|} - \mathrm{tr} \left[\Sigma_1^{-1} \left\langle (x - \mu_1)(x - \mu_1)^{\mathrm{T}} \right\rangle_{p(x)} \right] + \mathrm{tr} \left[\Sigma_2^{-1} \left\langle xx^{\mathrm{T}} - 2\mu_2 x^{\mathrm{T}} + \mu_2 \mu_2^{\mathrm{T}} \right\rangle_{p(x)} \right] \right) \\
&= \frac{1}{2} \left(\ln \frac{|\Sigma_2|}{|\Sigma_1|} - \mathrm{tr} \left[\Sigma_1^{-1} \left\langle (x - \mu_1)(x - \mu_1)^{\mathrm{T}} \right\rangle_{p(x)} \right] + \mathrm{tr} \left[\Sigma_2^{-1} \left(\left\langle xx^{\mathrm{T}} \right\rangle_{p(x)} - \left\langle 2\mu_2 x^{\mathrm{T}} \right\rangle_{p(x)} + \left\langle \mu_2 \mu_2^{\mathrm{T}} \right\rangle_{p(x)} \right) \right] \right)
\end{aligned}
\tag{7}
$$

Using the expectation of a linear form for the multivariate normal distribution ($\to$ Proof II/4.1.5)

$$
x \sim \mathcal{N}(\mu, \Sigma) \quad \Rightarrow \quad \langle Ax \rangle = A\mu \tag{8}
$$

and the expectation of a quadratic form for the multivariate normal distribution ($\to$ Proof I/1.5.8)

$$
x \sim \mathcal{N}(\mu, \Sigma) \quad \Rightarrow \quad \left\langle x^{\mathrm{T}} A x \right\rangle = \mu^{\mathrm{T}} A \mu + \mathrm{tr}(A\Sigma) \,, \tag{9}
$$

the Kullback-Leibler divergence from (7) becomes:

$$
\begin{aligned}
\mathrm{KL}[P \,||\, Q] &= \frac{1}{2} \left(\ln \frac{|\Sigma_2|}{|\Sigma_1|} - \mathrm{tr} \left[\Sigma_1^{-1} \Sigma_1 \right] + \mathrm{tr} \left[\Sigma_2^{-1} \left(\Sigma_1 + \mu_1 \mu_1^{\mathrm{T}} - 2\mu_2 \mu_1^{\mathrm{T}} + \mu_2 \mu_2^{\mathrm{T}} \right) \right] \right) \\
&= \frac{1}{2} \left(\ln \frac{|\Sigma_2|}{|\Sigma_1|} - \mathrm{tr} \left[I_n \right] + \mathrm{tr} \left[\Sigma_2^{-1} \Sigma_1 \right] + \mathrm{tr} \left[\Sigma_2^{-1} \left(\mu_1 \mu_1^{\mathrm{T}} - 2\mu_2 \mu_1^{\mathrm{T}} + \mu_2 \mu_2^{\mathrm{T}} \right) \right] \right) \\
&= \frac{1}{2} \left(\ln \frac{|\Sigma_2|}{|\Sigma_1|} - n + \mathrm{tr} \left[\Sigma_2^{-1} \Sigma_1 \right] + \mathrm{tr} \left[\mu_1^{\mathrm{T}} \Sigma_2^{-1} \mu_1 - 2\mu_1^{\mathrm{T}} \Sigma_2^{-1} \mu_2 + \mu_2^{\mathrm{T}} \Sigma_2^{-1} \mu_2 \right] \right) \\
&= \frac{1}{2} \left[\ln \frac{|\Sigma_2|}{|\Sigma_1|} - n + \mathrm{tr} \left[\Sigma_2^{-1} \Sigma_1 \right] + (\mu_2 - \mu_1)^T \Sigma_2^{-1} (\mu_2 - \mu_1) \right] \,.
\end{aligned}
\tag{10}
$$

Finally, rearranging the terms, we get:

$$
\mathrm{KL}[P \,||\, Q] = \frac{1}{2} \left[(\mu_2 - \mu_1)^T \Sigma_2^{-1} (\mu_2 - \mu_1) + \mathrm{tr}(\Sigma_2^{-1} \Sigma_1) - \ln \frac{|\Sigma_1|}{|\Sigma_2|} - n \right] \,. \tag{11}
$$

4.1.5 Linear transformation

Theorem: Let x follow a multivariate normal distribution ($\to$ Definition II/4.1.1):

$$
x \sim \mathcal{N}(\mu, \Sigma) \,. \tag{1}
$$

Then, any linear transformation of x is also multivariate normally distributed:

$$
y = Ax + b \sim \mathcal{N}(A\mu + b, A\Sigma A^{\mathrm{T}}) \,. \tag{2}
$$

Proof: The moment-generating function of a random vector ($\to$ Definition I/1.4.19) x is

$$M_x(t) = \mathbb{E}\left(\exp\left[t^{\mathrm{T}} x\right]\right) \tag{3}$$

and therefore the moment-generating function of the random vector y is given by

$$
\begin{aligned}
M_y(t) &\overset{(2)}{=} \mathbb{E}\left(\exp\left[t^{\mathrm{T}}(Ax + b)\right]\right) \\
&= \mathbb{E}\left(\exp\left[t^{\mathrm{T}} Ax\right] \cdot \exp\left[t^{\mathrm{T}} b\right]\right) \\
&= \exp\left[t^{\mathrm{T}} b\right] \cdot \mathbb{E}\left(\exp\left[t^{\mathrm{T}} Ax\right]\right) \\
&\overset{(3)}{=} \exp\left[t^{\mathrm{T}} b\right] \cdot M_x(At) \,.
\end{aligned}
\tag{4}
$$

The moment-generating function of the multivariate normal distribution ($\to$ Proof "mvn-mgf") is

$$M_x(t) = \exp\left[t^{\mathrm{T}} \mu + \frac{1}{2} t^{\mathrm{T}} \Sigma t\right] \tag{5}$$

and therefore the moment-generating function of the random vector y becomes

$$
\begin{aligned}
M_y(t) &\overset{(4)}{=} \exp\left[t^{\mathrm{T}} b\right] \cdot M_x(At) \\
&\overset{(5)}{=} \exp\left[t^{\mathrm{T}} b\right] \cdot \exp\left[t^{\mathrm{T}} A\mu + \frac{1}{2} t^{\mathrm{T}} A\Sigma A^{\mathrm{T}} t\right] \\
&= \exp\left[t^{\mathrm{T}} \left(A\mu + b\right) + \frac{1}{2} t^{\mathrm{T}} A\Sigma A^{\mathrm{T}} t\right] \,.
\end{aligned}
\tag{6}
$$

Because moment-generating function and probability density function of a random variable are equivalent, this demonstrates that y is following a multivariate normal distribution with mean $A\mu + b$ and covariance $A\Sigma A^{\mathrm{T}}$.

- Taboga, Marco (2010): "Linear combinations of normal random variables"; in: *Lectures on probability and statistics*, retrieved on 2019-08-27; URL: https://www.statlect.com/probability-distributions/normal-distribution-linear-combinations.

Metadata: ID: P1 | shortcut: mvn-ltt | author: JoramSoch | date: 2019-08-27, 12:14.

4.1.6 Marginal distributions

Theorem: Let x follow a multivariate normal distribution ($\to$ Definition II/4.1.1):

$$x \sim \mathcal{N}(\mu, \Sigma) \,. \tag{1}$$

Then, the marginal distribution ($\to$ Definition I/1.3.3) of any subset vector x_s is also a multivariate normal distribution

$$x_s \sim \mathcal{N}(\mu_s, \Sigma_s) \tag{2}$$

where μ_s drops the irrelevant variables (the ones not in the subset, i.e. marginalized out) from the mean vector μ and Σ_s drops the corresponding rows and columns from the covariance matrix Σ.

Proof: Define an $m \times n$ subset matrix S such that $s_{ij} = 1$, if the j-th element in μ_s corresponds to the i-th element in x, and $s_{ij} = 0$ otherwise. Then,

$$x_s = Sx \tag{3}$$

and we can apply the linear transformation theorem ($\rightarrow$ Proof II/4.1.5) to give

$$x_s \sim \mathcal{N}(S\mu, S\Sigma S^{\mathrm{T}}) . \tag{4}$$

Finally, we see that $S\mu = \mu_s$ and $S\Sigma S^{\mathrm{T}} = \Sigma_s$.

4.1.7   Conditional distributions

Theorem: Let x follow a multivariate normal distribution ($\rightarrow$ Definition II/4.1.1)

$$x \sim \mathcal{N}(\mu, \Sigma) . \tag{1}$$

Then, the conditional distribution ($\rightarrow$ Definition I/1.3.4) of any subset vector x_1, given the complement vector x_2, is also a multivariate normal distribution

$$x_1 | x_2 \sim \mathcal{N}(\mu_{1|2}, \Sigma_{1|2}) \tag{2}$$

where the conditional mean ($\rightarrow$ Definition I/1.5.1) and covariance ($\rightarrow$ Definition I/1.7.1) are

$$\begin{aligned}
\mu_{1|2} &= \mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(x_2 - \mu_2) \\
\Sigma_{1|2} &= \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}
\end{aligned} \tag{3}$$

with block-wise mean and covariance defined as

$$\begin{aligned}
\mu &= \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix} \\
\Sigma &= \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix} .
\end{aligned} \tag{4}$$

Proof: Without loss of generality, we assume that, in parallel to (4),

$$x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \tag{5}$$

where x_1 is an $n_1 \times 1$ vector, x_2 is an $n_2 \times 1$ vector and x is an $n_1 + n_2 = n \times 1$ vector.

By construction, the joint distribution ($\rightarrow$ Definition I/1.3.2) of x_1 and x_2 is:

$$x_1, x_2 \sim \mathcal{N}(\mu, \Sigma) \ . \tag{6}$$

Moreover, the marginal distribution ($\rightarrow$ Definition I/1.3.3) of x_2 follows from ($\rightarrow$ Proof II/4.1.6) (1) and (4) as

$$x_2 \sim \mathcal{N}(\mu_2, \Sigma_{22}) \ . \tag{7}$$

According to the law of conditional probability ($\rightarrow$ Definition I/1.2.4), it holds that

$$p(x_1|x_2) = \frac{p(x_1, x_2)}{p(x_2)} \tag{8}$$

Applying (6) and (7) to (8), we have:

$$p(x_1|x_2) = \frac{\mathcal{N}(x; \mu, \Sigma)}{\mathcal{N}(x_2; \mu_2, \Sigma_{22})} \ . \tag{9}$$

Using the probability density function of the multivariate normal distribution ($\rightarrow$ Proof II/4.1.2), this becomes:

$$
\begin{aligned}
p(x_1|x_2) &= \frac{1/\sqrt{(2\pi)^n |\Sigma|} \cdot \exp\left[-\frac{1}{2}(x-\mu)^{\mathrm{T}}\Sigma^{-1}(x-\mu)\right]}{1/\sqrt{(2\pi)^{n_2} |\Sigma_{22}|} \cdot \exp\left[-\frac{1}{2}(x_2-\mu_2)^{\mathrm{T}}\Sigma_{22}^{-1}(x_2-\mu_2)\right]} \\
&= \frac{1}{\sqrt{(2\pi)^{n-n_2}}} \cdot \sqrt{\frac{|\Sigma_{22}|}{|\Sigma|}} \cdot \exp\left[-\frac{1}{2}(x-\mu)^{\mathrm{T}}\Sigma^{-1}(x-\mu) + \frac{1}{2}(x_2-\mu_2)^{\mathrm{T}}\Sigma_{22}^{-1}(x_2-\mu_2)\right] \ .
\end{aligned} \tag{10}
$$

Writing the inverse of Σ as

$$\Sigma^{-1} = \begin{bmatrix} \Sigma^{11} & \Sigma^{12} \\ \Sigma^{21} & \Sigma^{22} \end{bmatrix} \tag{11}$$

and applying (4) to (10), we get:

$$
\begin{aligned}
p(x_1|x_2) = &\frac{1}{\sqrt{(2\pi)^{n-n_2}}} \cdot \sqrt{\frac{|\Sigma_{22}|}{|\Sigma|}} \cdot \\
&\exp\left[-\frac{1}{2}\left(\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} - \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix}\right)^{\mathrm{T}} \begin{bmatrix} \Sigma^{11} & \Sigma^{12} \\ \Sigma^{21} & \Sigma^{22} \end{bmatrix} \left(\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} - \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix}\right)\right. \\
&\left. + \frac{1}{2}(x_2-\mu_2)^{\mathrm{T}}\Sigma_{22}^{-1}(x_2-\mu_2)\right] \ .
\end{aligned} \tag{12}
$$

Multiplying out within the exponent of (12), we have

$$
\begin{aligned}
p(x_1|x_2) =& \frac{1}{\sqrt{(2\pi)^{n-n_2}}} \cdot \sqrt{\frac{|\Sigma_{22}|}{|\Sigma|}} \cdot \\
& \exp\left[-\frac{1}{2}\left((x_1-\mu_1)^{\mathrm{T}}\Sigma^{11}(x_1-\mu_1) + 2(x_1-\mu_1)^{\mathrm{T}}\Sigma^{12}(x_2-\mu_2) + (x_2-\mu_2)^{\mathrm{T}}\Sigma^{22}(x_2-\mu_2)\right)\right. \\
& \left.+\frac{1}{2}(x_2-\mu_2)^{\mathrm{T}}\Sigma_{22}^{-1}(x_2-\mu_2)\right]
\end{aligned}
\tag{13}
$$

where we have used the fact that $\Sigma^{21\,\mathrm{T}} = \Sigma^{12}$, because Σ^{-1} is a symmetric matrix.

The inverse of a block matrix is

$$
\begin{bmatrix} A & B \\ C & D \end{bmatrix}^{-1} = \begin{bmatrix} (A-BD^{-1}C)^{-1} & -(A-BD^{-1}C)^{-1}BD^{-1} \\ -D^{-1}C(A-BD^{-1}C)^{-1} & D^{-1}+D^{-1}C(A-BD^{-1}C)^{-1}BD^{-1} \end{bmatrix}, \tag{14}
$$

thus the inverse of Σ in (11) is

$$
\begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}^{-1} = \begin{bmatrix} (\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1} & -(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1}\Sigma_{12}\Sigma_{22}^{-1} \\ -\Sigma_{22}^{-1}\Sigma_{21}(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1} & \Sigma_{22}^{-1}+\Sigma_{22}^{-1}\Sigma_{21}(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1}\Sigma_{12}\Sigma_{22}^{-1} \end{bmatrix}. \tag{15}
$$

Plugging this into (13), we have:

$$
\begin{aligned}
p(x_1|x_2) =& \frac{1}{\sqrt{(2\pi)^{n-n_2}}} \cdot \sqrt{\frac{|\Sigma_{22}|}{|\Sigma|}} \cdot \\
& \exp\left[-\frac{1}{2}\left((x_1-\mu_1)^{\mathrm{T}}(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1}(x_1-\mu_1) - \right.\right. \\
& \qquad 2(x_1-\mu_1)^{\mathrm{T}}(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1}\Sigma_{12}\Sigma_{22}^{-1}(x_2-\mu_2)+ \\
& \qquad (x_2-\mu_2)^{\mathrm{T}}\left[\Sigma_{22}^{-1}+\Sigma_{22}^{-1}\Sigma_{21}(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1}\Sigma_{12}\Sigma_{22}^{-1}\right](x_2-\mu_2)) \\
& \left.\left.+\frac{1}{2}\left((x_2-\mu_2)^{\mathrm{T}}\Sigma_{22}^{-1}(x_2-\mu_2)\right)\right].
\end{aligned}
\tag{16}
$$

Eliminating some terms, we have:

$$
\begin{aligned}
p(x_1|x_2) =& \frac{1}{\sqrt{(2\pi)^{n-n_2}}} \cdot \sqrt{\frac{|\Sigma_{22}|}{|\Sigma|}} \cdot \\
& \exp\left[-\frac{1}{2}\left((x_1-\mu_1)^{\mathrm{T}}(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1}(x_1-\mu_1) - \right.\right. \\
& \qquad 2(x_1-\mu_1)^{\mathrm{T}}(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1}\Sigma_{12}\Sigma_{22}^{-1}(x_2-\mu_2)+ \\
& \qquad \left.\left.(x_2-\mu_2)^{\mathrm{T}}\Sigma_{22}^{-1}\Sigma_{21}(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1}\Sigma_{12}\Sigma_{22}^{-1}(x_2-\mu_2))\right].
\end{aligned}
\tag{17}
$$

Rearranging the terms, we have

$$
\begin{aligned}
p(x_1|x_2) =& \frac{1}{\sqrt{(2\pi)^{n-n_2}}} \cdot \sqrt{\frac{|\Sigma_{22}|}{|\Sigma|}} \cdot \exp\left[-\frac{1}{2}\cdot\right. \\
& \left. \left[(x_1 - \mu_1) - \Sigma_{12}^{\mathrm{T}}\Sigma_{22}^{-1}(x_2 - \mu_2)\right]^{\mathrm{T}} (\Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1} \left[(x_1 - \mu_1) - \Sigma_{12}^{\mathrm{T}}\Sigma_{22}^{-1}(x_2 - \mu_2)\right]\right] \\
=& \frac{1}{\sqrt{(2\pi)^{n-n_2}}} \cdot \sqrt{\frac{|\Sigma_{22}|}{|\Sigma|}} \cdot \exp\left[-\frac{1}{2}\cdot\right. \\
& \left. \left[x_1 - \left(\mu_1 + \Sigma_{12}^{\mathrm{T}}\Sigma_{22}^{-1}(x_2 - \mu_2)\right)\right]^{\mathrm{T}} (\Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1} \left[x_1 - \left(\mu_1 + \Sigma_{12}^{\mathrm{T}}\Sigma_{22}^{-1}(x_2 - \mu_2)\right)\right]\right]
\end{aligned}
$$
$$(18)$$

where we have used the fact that $\Sigma_{21}^{\mathrm{T}} = \Sigma_{12}$, because Σ is a covariance matrix.

The determinant of a block matrix is

$$
\begin{vmatrix} A & B \\ C & D \end{vmatrix} = |D| \cdot |A - BD^{-1}C| \, ,
\tag{19}
$$

such that we have for Σ that

$$
\begin{vmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{vmatrix} = |\Sigma_{22}| \cdot |\Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}| \, .
\tag{20}
$$

With this and $n - n_2 = n_1$, we finally arrive at

$$
\begin{aligned}
p(x_1|x_2) =& \frac{1}{\sqrt{(2\pi)^{n_1}|\Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}|}} \cdot \exp\left[-\frac{1}{2}\cdot\right. \\
& \left. \left[x_1 - \left(\mu_1 + \Sigma_{12}^{\mathrm{T}}\Sigma_{22}^{-1}(x_2 - \mu_2)\right)\right]^{\mathrm{T}} (\Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1} \left[x_1 - \left(\mu_1 + \Sigma_{12}^{\mathrm{T}}\Sigma_{22}^{-1}(x_2 - \mu_2)\right)\right]\right]
\end{aligned}
$$
$$(21)$$

which is the probability density function of a multivariate normal distribution ($\rightarrow$ Proof II/4.1.2)

$$
p(x_1|x_2) = \mathcal{N}(x_1; \mu_{1|2}, \Sigma_{1|2})
\tag{22}
$$

with the mean $\mu_{1|2}$ and variance $\Sigma_{1|2}$ given by (3).

4.2   Multivariate t-distribution

4.2.1   Definition

Definition: Let X be an $n \times 1$ random vector ($\to$ Definition I/1.1.4). Then, X is said to follow a multivariate t-distribution with mean μ, scale matrix Σ and degrees of freedom ν

$$X \sim t(\mu, \Sigma, \nu) \; , \tag{1}$$

if and only if its probability density function ($\to$ Definition I/1.4.4) is given by

$$t(x; \mu, \Sigma, \nu) = \sqrt{\frac{1}{(\nu\pi)^n |\Sigma|}} \frac{\Gamma([\nu+n]/2)}{\Gamma(\nu/2)} \left[1 + \frac{1}{\nu}(x-\mu)^{\mathrm{T}} \Sigma^{-1} (x-\mu) \right] \tag{2}$$

where μ is an $n \times 1$ real vector, Σ is an $n \times n$ positive definite matrix and $\nu > 0$.

4.3   Normal-gamma distribution

4.3.1   Definition

Definition: Let X be an $n \times 1$ random vector ($\to$ Definition I/1.1.4) and let Y be a positive random variable ($\to$ Definition I/1.1.3). Then, X and Y are said to follow a normal-gamma distribution

$$X, Y \sim \mathrm{NG}(\mu, \Lambda, a, b) \; , \tag{1}$$

if and only if their joint probability ($\to$ Definition I/1.2.2) density function ($\to$ Definition I/1.4.4) is given by

$$f_{X,Y}(x,y) = \mathcal{N}(x; \mu, (y\Lambda)^{-1}) \cdot \mathrm{Gam}(y; a, b) \tag{2}$$

where $\mathcal{N}(x; \mu, \Sigma)$ is the probability density function of the multivariate normal distribution ($\to$ Proof II/4.1.2) with mean μ and covariance Σ and $\mathrm{Gam}(x; a, b)$ is the probability density function of the gamma distribution ($\to$ Proof II/3.4.5) with shape a and rate b. The $n \times n$ matrix Λ is referred to as the precision matrix ($\to$ Definition I/1.7.9) of the normal-gamma distribution.

4.3.2 Probability density function

Theorem: Let x and y follow a normal-gamma distribution ($\rightarrow$ Definition II/4.3.1):

$$x, y \sim \text{NG}(\mu, \Lambda, a, b) \ . \tag{1}$$

Then, the joint probability ($\rightarrow$ Definition I/1.2.2) density function ($\rightarrow$ Definition I/1.4.4) of x and y is

$$p(x, y) = \sqrt{\frac{|\Lambda|}{(2\pi)^n}} \frac{b^a}{\Gamma(a)} \cdot y^{a+\frac{n}{2}-1} \exp\left[-\frac{y}{2}\left((x-\mu)^{\text{T}}\Lambda(x-\mu) + 2b\right)\right] \ . \tag{2}$$

Proof: The probability density of the normal-gamma distribution is defined as ($\rightarrow$ Definition II/4.3.1) as the product of a multivariate normal distribution ($\rightarrow$ Definition II/4.1.1) over x conditional on y and a univariate gamma distribution ($\rightarrow$ Definition II/3.4.1) over y:

$$p(x, y) = \mathcal{N}(x; \mu, (y\Lambda)^{-1}) \cdot \text{Gam}(y; a, b) \tag{3}$$

With the probability density function of the multivariate normal distribution ($\rightarrow$ Proof II/4.1.2) and the probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5), this becomes:

$$p(x, y) = \sqrt{\frac{|y\Lambda|}{(2\pi)^n}} \exp\left[-\frac{1}{2}(x-\mu)^{\text{T}}(y\Lambda)(x-\mu)\right] \cdot \frac{b^a}{\Gamma(a)} y^{a-1} \exp\left[-by\right] \ . \tag{4}$$

Using the relation $|yA| = y^n|A|$ for an $n \times n$ matrix A and rearranging the terms, we have:

$$p(x, y) = \sqrt{\frac{|\Lambda|}{(2\pi)^n}} \frac{b^a}{\Gamma(a)} \cdot y^{a+\frac{n}{2}-1} \exp\left[-\frac{y}{2}\left((x-\mu)^{\text{T}}\Lambda(x-\mu) + 2b\right)\right] \ . \tag{5}$$

Sources:
- Koch KR (2007): "Normal-Gamma Distribution"; in: *Introduction to Bayesian Statistics*, ch. 2.5.3, pp. 55-56, eq. 2.212; URL: https://www.springer.com/gp/book/9783540727231; DOI: 10.1007/978-3-540-72726-2.

4.3.3 Kullback-Leibler divergence

Theorem: Let x be an $n \times 1$ random vector ($\rightarrow$ Definition I/1.1.4) and let y be a positive random variable ($\rightarrow$ Definition I/1.1.3). Assume two normal-gamma distributions ($\rightarrow$ Definition II/4.3.1) P and Q specifying the joint distribution of x and y as

$$\begin{aligned} P &: \ (x, y) \sim \text{NG}(\mu_1, \Lambda_1^{-1}, a_1, b_1) \\ Q &: \ (x, y) \sim \text{NG}(\mu_2, \Lambda_2^{-1}, a_2, b_2) \ . \end{aligned} \tag{1}$$

Then, the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) of P from Q is given by

$$\mathrm{KL}[P \,||\, Q] = \frac{1}{2}\frac{a_1}{b_1}\left[(\mu_2 - \mu_1)^T \Lambda_2 (\mu_2 - \mu_1)\right] + \frac{1}{2}\,\mathrm{tr}(\Lambda_2 \Lambda_1^{-1}) - \frac{1}{2}\ln\frac{|\Lambda_2|}{|\Lambda_1|} - \frac{n}{2}$$
$$+ a_2 \ln\frac{b_1}{b_2} - \ln\frac{\Gamma(a_1)}{\Gamma(a_2)} + (a_1 - a_2)\,\psi(a_1) - (b_1 - b_2)\frac{a_1}{b_1}\,. \tag{2}$$

Proof: The probability density function of the normal-gamma distribution ($\rightarrow$ Proof II/4.3.2) is

$$p(x, y) = p(x|y) \cdot p(y) = \mathcal{N}(x; \mu, (y\Lambda)^{-1}) \cdot \mathrm{Gam}(y; a, b)\,. \tag{3}$$

The Kullback-Leibler divergence of the multivariate normal distribution ($\rightarrow$ Proof II/4.1.4) is

$$\mathrm{KL}[P \,||\, Q] = \frac{1}{2}\left[(\mu_2 - \mu_1)^T \Sigma_2^{-1}(\mu_2 - \mu_1) + \mathrm{tr}(\Sigma_2^{-1}\Sigma_1) - \ln\frac{|\Sigma_1|}{|\Sigma_2|} - n\right] \tag{4}$$

and the Kullback-Leibler divergence of the univariate gamma distribution ($\rightarrow$ Proof II/3.4.12) is

$$\mathrm{KL}[P \,||\, Q] = a_2 \ln\frac{b_1}{b_2} - \ln\frac{\Gamma(a_1)}{\Gamma(a_2)} + (a_1 - a_2)\,\psi(a_1) - (b_1 - b_2)\frac{a_1}{b_1} \tag{5}$$

where $\Gamma(x)$ is the gamma function and $\psi(x)$ is the digamma function.

The KL divergence for a continuous random variable ($\rightarrow$ Definition I/2.5.1) is given by

$$\mathrm{KL}[P \,||\, Q] = \int_{\mathcal{Z}} p(z)\,\ln\frac{p(z)}{q(z)}\,\mathrm{d}z \tag{6}$$

which, applied to the normal-gamma distribution ($\rightarrow$ Definition II/4.3.1) over x and y, yields

$$\mathrm{KL}[P \,||\, Q] = \int_0^\infty \int_{\mathbb{R}^n} p(x, y)\,\ln\frac{p(x, y)}{q(x, y)}\,\mathrm{d}x\,\mathrm{d}y\,. \tag{7}$$

Using the law of conditional probability ($\rightarrow$ Definition I/1.2.4), this can be evaluated as follows:

$$\begin{aligned}
\mathrm{KL}[P \,||\, Q] &= \int_0^\infty \int_{\mathbb{R}^n} p(x|y)\,p(y)\,\ln\frac{p(x|y)\,p(y)}{q(x|y)\,q(y)}\,\mathrm{d}x\,\mathrm{d}y \\
&= \int_0^\infty \int_{\mathbb{R}^n} p(x|y)\,p(y)\,\ln\frac{p(x|y)}{q(x|y)}\,\mathrm{d}x\,\mathrm{d}y + \int_0^\infty \int_{\mathbb{R}^n} p(x|y)\,p(y)\,\ln\frac{p(y)}{q(y)}\,\mathrm{d}x\,\mathrm{d}y \\
&= \int_0^\infty p(y) \int_{\mathbb{R}^n} p(x|y)\,\ln\frac{p(x|y)}{q(x|y)}\,\mathrm{d}x\,\mathrm{d}y + \int_0^\infty p(y)\,\ln\frac{p(y)}{q(y)} \int_{\mathbb{R}^n} p(x|y)\,\mathrm{d}x\,\mathrm{d}y \\
&= \langle \mathrm{KL}[p(x|y) \,||\, q(x|y)]\rangle_{p(y)} + \mathrm{KL}[p(y) \,||\, q(y)]\,.
\end{aligned} \tag{8}$$

In other words, the KL divergence between two normal-gamma distributions over x and y is equal to the sum of a multivariate normal KL divergence regarding x conditional on y, expected over y, and a univariate gamma KL divergence regarding y.

From equations (3) and (4), the first term becomes

$$\langle \text{KL}[p(x|y) \,||\, q(x|y)]\rangle_{p(y)}$$

$$= \left\langle \frac{1}{2} \left[(\mu_2 - \mu_1)^T (y\Lambda_2)(\mu_2 - \mu_1) + \text{tr}\left((y\Lambda_2)(y\Lambda_1)^{-1}\right) - \ln \frac{|(y\Lambda_1)^{-1}|}{|(y\Lambda_2)^{-1}|} - n \right] \right\rangle_{p(y)} \quad (9)$$

$$= \left\langle \frac{y}{2} (\mu_2 - \mu_1)^T \Lambda_2 (\mu_2 - \mu_1) + \frac{1}{2} \text{tr}(\Lambda_2 \Lambda_1^{-1}) - \frac{1}{2} \ln \frac{|\Lambda_2|}{|\Lambda_1|} - \frac{n}{2} \right\rangle_{p(y)}$$

and using the relation ($\rightarrow$ Proof II/3.4.8) $y \sim \text{Gam}(a,b) \Rightarrow \langle y \rangle = a/b$, we have

$$\langle \text{KL}[p(x|y) \,||\, q(x|y)]\rangle_{p(y)} = \frac{1}{2}\frac{a_1}{b_1}(\mu_2 - \mu_1)^T \Lambda_2 (\mu_2 - \mu_1) + \frac{1}{2} \text{tr}(\Lambda_2 \Lambda_1^{-1}) - \frac{1}{2} \ln \frac{|\Lambda_2|}{|\Lambda_1|} - \frac{n}{2} \,. \quad (10)$$

By plugging (10) and (5) into (8), one arrives at the KL divergence given by (2).

4.3.4 Marginal distributions

Theorem: Let x and y follow a normal-gamma distribution ($\rightarrow$ Definition II/4.3.1):

$$x, y \sim \text{NG}(\mu, \Lambda, a, b) \,. \quad (1)$$

Then, the marginal distribution ($\rightarrow$ Definition I/1.3.3) of y is a gamma distribution ($\rightarrow$ Definition II/3.4.1)

$$y \sim \text{Gam}(a, b) \quad (2)$$

and the marginal distribution ($\rightarrow$ Definition I/1.3.3) of x is a multivariate t-distribution ($\rightarrow$ Definition II/4.2.1)

$$x \sim \text{t}\left(\mu, \left(\frac{a}{b}\Lambda\right)^{-1}, 2a\right) \,. \quad (3)$$

Proof: The probability density function of the normal-gamma distribution ($\rightarrow$ Proof II/4.3.2) is given by

$$p(x, y) = p(x|y) \cdot p(y)$$
$$p(x|y) = \mathcal{N}(x; \mu, (y\Lambda)^{-1}) \quad (4)$$
$$p(y) = \text{Gam}(y; a, b) \,.$$

Using the law of marginal probability ($\rightarrow$ Definition I/1.2.3), the marginal distribution of y can be derived as

$$
\begin{aligned}
p(y) &= \int p(x, y)\,\mathrm{d}x \\
&= \int \mathcal{N}(x; \mu, (y\Lambda)^{-1})\,\mathrm{Gam}(y; a, b)\,\mathrm{d}x \\
&= \mathrm{Gam}(y; a, b) \int \mathcal{N}(x; \mu, (y\Lambda)^{-1})\,\mathrm{d}x \\
&= \mathrm{Gam}(y; a, b)
\end{aligned}
\tag{5}
$$

which is the probability density function of the gamma distribution ($\to$ Proof II/3.4.5) with shape parameter a and rate parameter b.

Using the law of marginal probability ($\to$ Definition I/1.2.3), the marginal distribution of x can be derived as

$$p(x) = \int p(x, y)\, \mathrm{d}y$$

$$= \int \mathcal{N}(x; \mu, (y\Lambda)^{-1})\, \mathrm{Gam}(y; a, b)\, \mathrm{d}y$$

$$= \int \sqrt{\frac{|y\Lambda|}{(2\pi)^n}}\, \exp\left[-\frac{1}{2}(x-\mu)^{\mathrm{T}}(y\Lambda)(x-\mu)\right] \cdot \frac{b^a}{\Gamma(a)}\, y^{a-1} \exp[-by]\, \mathrm{d}y$$

$$= \int \sqrt{\frac{y^n|\Lambda|}{(2\pi)^n}}\, \exp\left[-\frac{1}{2}(x-\mu)^{\mathrm{T}}(y\Lambda)(x-\mu)\right] \cdot \frac{b^a}{\Gamma(a)}\, y^{a-1} \exp[-by]\, \mathrm{d}y$$

$$= \int \sqrt{\frac{|\Lambda|}{(2\pi)^n}} \cdot \frac{b^a}{\Gamma(a)} \cdot y^{a+\frac{n}{2}-1} \cdot \exp\left[-\left(b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)y\right]\, \mathrm{d}y$$

$$= \int \sqrt{\frac{|\Lambda|}{(2\pi)^n}} \cdot \frac{b^a}{\Gamma(a)} \cdot \frac{\Gamma\left(a+\frac{n}{2}\right)}{\left(b+\frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{a+\frac{n}{2}}} \cdot \mathrm{Gam}\left(y; a+\frac{n}{2}, b+\frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)\, \mathrm{d}y$$

$$= \sqrt{\frac{|\Lambda|}{(2\pi)^n}} \cdot \frac{b^a}{\Gamma(a)} \cdot \frac{\Gamma\left(a+\frac{n}{2}\right)}{\left(b+\frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{a+\frac{n}{2}}} \int \mathrm{Gam}\left(y; a+\frac{n}{2}, b+\frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)\, \mathrm{d}y$$

$$= \sqrt{\frac{|\Lambda|}{(2\pi)^n}} \cdot \frac{b^a}{\Gamma(a)} \cdot \frac{\Gamma\left(a+\frac{n}{2}\right)}{\left(b+\frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{a+\frac{n}{2}}}$$

$$= \frac{\sqrt{|\Lambda|}}{(2\pi)^{\frac{n}{2}}} \cdot \frac{\Gamma\left(\frac{2a+n}{2}\right)}{\Gamma\left(\frac{2a}{2}\right)} \cdot b^a \cdot \left(b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{-\left(a+\frac{n}{2}\right)}$$

$$= \frac{\sqrt{|\Lambda|}}{\pi^{\frac{n}{2}}} \cdot \frac{\Gamma\left(\frac{2a+n}{2}\right)}{\Gamma\left(\frac{2a}{2}\right)} \cdot \left(\frac{1}{b}\right)^{-a} \cdot \left(b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{-a} \cdot 2^{-\frac{n}{2}} \cdot \left(b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{-\frac{n}{2}}$$

$$= \frac{\sqrt{|\Lambda|}}{\pi^{\frac{n}{2}}} \cdot \frac{\Gamma\left(\frac{2a+n}{2}\right)}{\Gamma\left(\frac{2a}{2}\right)} \cdot \left(1 + \frac{1}{2b}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{-a} \cdot \left(2b + (x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{-\frac{n}{2}}$$

$$= \frac{\sqrt{|\Lambda|}}{\pi^{\frac{n}{2}}} \cdot \frac{\Gamma\left(\frac{2a+n}{2}\right)}{\Gamma\left(\frac{2a}{2}\right)} \cdot \left(\frac{1}{2a}\right)^{-a} \cdot \left(2a + (x-\mu)^{\mathrm{T}}\left(\frac{a}{b}\Lambda\right)(x-\mu)\right)^{-a} \cdot \left(\frac{b}{a}\right)^{-\frac{n}{2}} \cdot \left(2a + (x-\mu)^{\mathrm{T}}\left(\frac{a}{b}\Lambda\right)(x-\mu)\right.$$

$$= \frac{\sqrt{\left(\frac{a}{b}\right)^n|\Lambda|}}{(2a)^{-a}\pi^{\frac{n}{2}}} \cdot \frac{\Gamma\left(\frac{2a+n}{2}\right)}{\Gamma\left(\frac{2a}{2}\right)} \cdot \left(2a + (x-\mu)^{\mathrm{T}}\left(\frac{a}{b}\Lambda\right)(x-\mu)\right)^{-a} \cdot \left(2a + (x-\mu)^{\mathrm{T}}\left(\frac{a}{b}\Lambda\right)(x-\mu)\right)^{-\frac{n}{2}}$$

$$= \frac{\sqrt{\left(\frac{a}{b}\right)^n|\Lambda|}}{(2a)^{-a}\pi^{\frac{n}{2}}} \cdot \frac{\Gamma\left(\frac{2a+n}{2}\right)}{\Gamma\left(\frac{2a}{2}\right)} \cdot (2a)^{-a} \cdot \left(1 + \frac{1}{2a}(x-\mu)^{\mathrm{T}}\left(\frac{a}{b}\Lambda\right)(x-\mu)\right)^{-a} \cdot (2a)^{-\frac{n}{2}} \cdot \left(1 + \frac{1}{2a}(x-\mu)^{\mathrm{T}}\left(\frac{a}{b}\Lambda\right)\right.$$

$$= \frac{\sqrt{\left(\frac{a}{b}\right)^n|\Lambda|}}{(2a)^{\frac{n}{2}}\pi^{\frac{n}{2}}} \cdot \frac{\Gamma\left(\frac{2a+n}{2}\right)}{\Gamma\left(\frac{2a}{2}\right)} \cdot \left(1 + \frac{1}{2a}(x-\mu)^{\mathrm{T}}\left(\frac{a}{b}\Lambda\right)(x-\mu)\right)^{-\frac{2a+n}{2}}$$

$$= \sqrt{\frac{\left|\frac{a}{b}\Lambda\right|}{(2a\,\pi)^n}} \cdot \frac{\Gamma\left(\frac{2a+n}{2}\right)}{\Gamma\left(\frac{2a}{2}\right)} \cdot \left(1 + \frac{1}{2a}(x-\mu)^{\mathrm{T}}\left(\frac{a}{b}\Lambda\right)(x-\mu)\right)^{-\frac{2a+n}{2}}$$

$$(6)$$

which is the probability density function of a multivariate t-distribution ($\rightarrow$ Proof "mvt-pdf") with mean vector μ, shape matrix $\left(\frac{a}{b}\Lambda\right)^{-1}$ and $2a$ degrees of freedom.

4.3.5   Conditional distributions

Theorem: Let x and y follow a normal-gamma distribution ($\to$ Definition II/4.3.1):

$$x, y \sim \mathrm{NG}(\mu, \Lambda, a, b) \; . \tag{1}$$

Then,
1) the conditional distribution ($\to$ Definition I/1.3.4) of x given y is a multivariate normal distribution ($\to$ Definition II/4.1.1)

$$x|y \sim \mathcal{N}(\mu, (y\Lambda)^{-1}) \; ; \tag{2}$$

2) the conditional distribution ($\to$ Definition I/1.3.4) of a subset vector x_1, given the complement vector x_2 and y, is also a multivariate normal distribution ($\to$ Definition II/4.1.1)

$$x_1|x_2, y \sim \mathcal{N}(\mu_{1|2}(y), \Sigma_{1|2}(y)) \tag{3}$$

with the conditional mean ($\to$ Definition I/1.5.1) and covariance ($\to$ Definition I/1.7.1)

$$\begin{aligned}
\mu_{1|2}(y) &= \mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(x_2 - \mu_2) \\
\Sigma_{1|2}(y) &= \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{12}
\end{aligned} \tag{4}$$

where μ_1, μ_2 and Σ_{11}, Σ_{12}, Σ_{22}, Σ_{21} are block-wise components ($\to$ Proof II/4.1.7) of μ and $\Sigma(y) = (y\Lambda)^{-1}$;

3) the conditional distribution ($\to$ Definition I/1.3.4) of y given x is a gamma distribution ($\to$ Definition II/3.4.1)

$$y|x \sim \mathrm{Gam}\left(a + \frac{n}{2}, b + \frac{1}{2}(x - \mu)^{\mathrm{T}}\Lambda(x - \mu)\right) \tag{5}$$

where n is the dimensionality of x.

Proof:
1) This follows from the definition of the normal-gamma distribution ($\to$ Definition II/4.3.1):

$$\begin{aligned}
p(x, y) &= p(x|y) \cdot p(y) \\
&= \mathcal{N}(x; \mu, (y\Lambda)^{-1}) \cdot \mathrm{Gam}(y; a, b) \; .
\end{aligned} \tag{6}$$

2) This follows from (2) and the conditional distributions of the multivariate normal distribution ($\to$ Proof II/4.1.7):

$$\begin{aligned}
x &\sim \mathcal{N}(\mu, \Sigma) \\
\Rightarrow x_1|x_2 &\sim \mathcal{N}(\mu_{1|2}, \Sigma_{1|2}) \\
\mu_{1|2} &= \mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(x_2 - \mu_2) \\
\Sigma_{1|2} &= \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21} \; .
\end{aligned} \tag{7}$$

3) The conditional density of y given x follows from Bayes' theorem ($\to$ Proof I/5.3.1) as

$$p(y|x) = \frac{p(x|y) \cdot p(y)}{p(x)} \, . \tag{8}$$

The conditional distribution ($\to$ Definition I/1.3.4) of x given y is a multivariate normal distribution ($\to$ Proof II/4.3.2)

$$p(x|y) = \mathcal{N}(x; \mu, (y\Lambda)^{-1}) = \sqrt{\frac{|y\Lambda|}{(2\pi)^n}} \exp\left[-\frac{1}{2}(x-\mu)^{\mathrm{T}}(y\Lambda)(x-\mu)\right] , \tag{9}$$

the marginal distribution ($\to$ Definition I/1.3.3) of y is a gamma distribution ($\to$ Proof II/4.3.4)

$$p(y) = \mathrm{Gam}(y; a, b) = \frac{b^a}{\Gamma(a)} y^{a-1} \exp\left[-by\right] \tag{10}$$

and the marginal distribution ($\to$ Definition I/1.3.3) of x is a multivariate t-distribution ($\to$ Proof II/4.3.4)

$$\begin{aligned}
p(x) &= \mathrm{t}\left(x; \mu, \left(\frac{a}{b}\Lambda\right)^{-1}, 2a\right) \\
&= \sqrt{\frac{|\frac{a}{b}\Lambda|}{(2a\,\pi)^n}} \cdot \frac{\Gamma\left(\frac{2a+n}{2}\right)}{\Gamma\left(\frac{2a}{2}\right)} \cdot \left(1 + \frac{1}{2a}(x-\mu)^{\mathrm{T}}\left(\frac{a}{b}\Lambda\right)(x-\mu)\right)^{-\frac{2a+n}{2}} \\
&= \sqrt{\frac{|\Lambda|}{(2\pi)^n}} \cdot \frac{\Gamma\left(a+\frac{n}{2}\right)}{\Gamma(a)} \cdot b^a \cdot \left(b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{-\left(a+\frac{n}{2}\right)} .
\end{aligned} \tag{11}$$

Plugging (9), (10) and (11) into (8), we obtain

$$\begin{aligned}
p(y|x) &= \frac{\sqrt{\frac{|y\Lambda|}{(2\pi)^n}} \exp\left[-\frac{1}{2}(x-\mu)^{\mathrm{T}}(y\Lambda)(x-\mu)\right] \cdot \frac{b^a}{\Gamma(a)} y^{a-1} \exp\left[-by\right]}{\sqrt{\frac{|\Lambda|}{(2\pi)^n}} \cdot \frac{\Gamma\left(a+\frac{n}{2}\right)}{\Gamma(a)} \cdot b^a \cdot \left(b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{-\left(a+\frac{n}{2}\right)}} \\
&= y^{\frac{n}{2}} \cdot \exp\left[-\frac{1}{2}(x-\mu)^{\mathrm{T}}(y\Lambda)(x-\mu)\right] \cdot y^{a-1} \cdot \exp\left[-by\right] \cdot \frac{1}{\Gamma\left(a+\frac{n}{2}\right)} \cdot \left(b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{a+\frac{n}{2}} \\
&= \frac{\left(b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)^{a+\frac{n}{2}}}{\Gamma\left(a+\frac{n}{2}\right)} \cdot y^{a+\frac{n}{2}-1} \cdot \exp\left[-\left(b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right)\right]
\end{aligned} \tag{12}$$

which is the probability density function of a gamma distribution ($\to$ Proof II/3.4.5) with shape and rate parameters

$$a + \frac{n}{2} \quad \text{and} \quad b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu) \, , \tag{13}$$

such that

$$p(y|x) = \mathrm{Gam}\left(y; a + \frac{n}{2}, b + \frac{1}{2}(x-\mu)^{\mathrm{T}}\Lambda(x-\mu)\right) \, . \tag{14}$$

4.4   Dirichlet distribution

4.4.1   Definition

Definition: Let X be a random vector ($\rightarrow$ Definition I/1.1.4). Then, X is said to follow a Dirichlet distribution with concentration parameters $\alpha = [\alpha_1, \ldots, \alpha_k]$

$$X \sim \mathrm{Dir}(\alpha) \, , \tag{1}$$

if and only if its probability density function ($\rightarrow$ Definition I/1.4.4) is given by

$$\mathrm{Dir}(x; \alpha) = \frac{\Gamma\left(\sum_{i=1}^{k} \alpha_i\right)}{\prod_{i=1}^{k} \Gamma(\alpha_i)} \prod_{i=1}^{k} x_i^{\alpha_i - 1} \tag{2}$$

where $\alpha_i > 0$ for all $i = 1, \ldots, k$, and the density is zero, if $x_i \notin [0, 1]$ for any $i = 1, \ldots, k$ or $\sum_{i=1}^{k} x_i \neq 1$.

4.4.2   Probability density function

Theorem: Let X be a random vector ($\rightarrow$ Definition I/1.1.4) following a Dirichlet distribution ($\rightarrow$ Definition II/4.4.1):

$$X \sim \mathrm{Dir}(\alpha) \, . \tag{1}$$

Then, the probability density function ($\rightarrow$ Definition I/1.4.4) of X is

$$f_X(x) = \frac{\Gamma\left(\sum_{i=1}^{k} \alpha_i\right)}{\prod_{i=1}^{k} \Gamma(\alpha_i)} \prod_{i=1}^{k} x_i^{\alpha_i - 1} \, . \tag{2}$$

Proof: This follows directly from the definition of the Dirichlet distribution ($\rightarrow$ Definition II/4.4.1).

4.4.3 Exceedance probabilities

Theorem: Let $r = [r_1, \ldots, r_k]$ be a random vector ($\rightarrow$ Definition I/1.1.4) following a Dirichlet distribution ($\rightarrow$ Definition II/4.4.1) with concentration parameters $\alpha = [\alpha_1, \ldots, \alpha_k]$:

$$r \sim \text{Dir}(\alpha) \ . \tag{1}$$

1) If $k = 2$, then the exceedance probability ($\rightarrow$ Definition I/1.2.5) for r_1 is

$$\varphi_1 = 1 - \frac{\text{B}\left(\frac{1}{2}; \alpha_1, \alpha_2\right)}{\text{B}(\alpha_1, \alpha_2)} \tag{2}$$

where $\text{B}(x, y)$ is the beta function and $\text{B}(x; a, b)$ is the incomplete beta function.

2) If $k > 2$, then the exceedance probability ($\rightarrow$ Definition I/1.2.5) for r_i is

$$\varphi_i = \int_0^\infty \prod_{j \neq i} \left(\frac{\gamma(\alpha_j, q_i)}{\Gamma(\alpha_j)}\right) \frac{q_i^{\alpha_i - 1} \exp[-q_i]}{\Gamma(\alpha_i)} \, dq_i \ . \tag{3}$$

where $\Gamma(x)$ is the gamma function and $\gamma(s, x)$ is the lowerr incomplete gamma function.

Proof: In the context of the Dirichlet distribution ($\rightarrow$ Definition II/4.4.1), the exceedance probability ($\rightarrow$ Definition I/1.2.5) for a particular r_i is defined as:

$$\begin{aligned}
\varphi_i &= p\left(\forall j \in \left\{1, \ldots, k \mid j \neq i\right\} : r_i > r_j | \alpha\right) \\
&= p\left(\bigwedge_{j \neq i} r_i > r_j \mid \alpha\right) \ .
\end{aligned} \tag{4}$$

The probability density function of the Dirichlet distribution ($\rightarrow$ Proof II/4.4.2) is given by:

$$\text{Dir}(r; \alpha) = \frac{\Gamma\left(\sum_{i=1}^k \alpha_i\right)}{\prod_{i=1}^k \Gamma(\alpha_i)} \prod_{i=1}^k r_i^{\alpha_i - 1} \ . \tag{5}$$

Note that the probability density function is only calculated, if

$$r_i \in [0, 1] \quad \text{for} \quad i = 1, \ldots, k \quad \text{and} \quad \sum_{i=1}^k r_i = 1 \ , \tag{6}$$

and defined to be zero otherwise ($\rightarrow$ Definition II/4.4.1).

1) If $k = 2$, the probability density function of the Dirichlet distribution ($\rightarrow$ Proof II/4.4.2) reduces to

$$p(r) = \frac{\Gamma(\alpha_1 + \alpha_2)}{\Gamma(\alpha_1)\,\Gamma(\alpha_2)} r_1^{\alpha_1 - 1} \, r_2^{\alpha_2 - 1} \tag{7}$$

which is equivalent to the probability density function of the beta distribution ($\rightarrow$ Proof II/3.8.2)

$$p(r_1) = \frac{r_1^{\alpha_1 - 1} (1 - r_1)^{\alpha_2 - 1}}{\text{B}(\alpha_1, \alpha_2)} \tag{8}$$

with the beta function given by

$$\mathrm{B}(x, y) = \frac{\Gamma(x)\,\Gamma(y)}{\Gamma(x+y)} \; . \tag{9}$$

With (6), the exceedance probability for this bivariate case simplifies to

$$\varphi_1 = p(r_1 > r_2) = p(r_1 > 1 - r_1) = p(r_1 > 1/2) = \int_{\frac{1}{2}}^{1} p(r_1)\,\mathrm{d}r_1 \; . \tag{10}$$

Using the cumulative distribution function of the beta distribution ($\rightarrow$ Proof II/3.8.4), it evaluates to

$$\varphi_1 = 1 - \int_0^{\frac{1}{2}} p(r_1)\,\mathrm{d}r_1 = 1 - \frac{\mathrm{B}\left(\frac{1}{2}; \alpha_1, \alpha_2\right)}{\mathrm{B}(\alpha_1, \alpha_2)} \tag{11}$$

with the incomplete beta function

$$\mathrm{B}(x; a, b) = \int_0^x x^{a-1}\,(1-x)^{b-1}\,\mathrm{d}x \; . \tag{12}$$

2) If $k > 2$, there is no similarly simple expression, because in general

$$\varphi_i = p(r_i = \max(r)) > p(r_i > 1/2) \quad \text{for} \quad i = 1, \ldots, k \; , \tag{13}$$

i.e. exceedance probabilities cannot be evaluated using a simple threshold on r_i, because r_i might be the maximal element in r without being larger than $1/2$. Instead, we make use of the relationship between the Dirichlet and the gamma distribution ($\rightarrow$ Proof "gam-dir") which states that

$$Y_1 \sim \mathrm{Gam}(\alpha_1, \beta), \; \ldots, \; Y_k \sim \mathrm{Gam}(\alpha_k, \beta), \; Y_s = \sum_{i=1}^{k} Y_j$$
$$\Rightarrow X = (X_1, \ldots, X_k) = \left(\frac{Y_1}{Y_s}, \ldots, \frac{Y_k}{Y_s}\right) \sim \mathrm{Dir}(\alpha_1, \ldots, \alpha_k) \; . \tag{14}$$

The probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5) is given by

$$\mathrm{Gam}(x; a, b) = \frac{b^a}{\Gamma(a)}\,x^{a-1}\,\exp[-bx] \quad \text{for} \quad x > 0 \; . \tag{15}$$

Consider the gamma random variables ($\rightarrow$ Definition II/3.4.1)

$$q_1 \sim \mathrm{Gam}(\alpha_1, 1), \; \ldots, \; q_k \sim \mathrm{Gam}(\alpha_k, 1), \; q_s = \sum_{j=1}^{k} q_j \tag{16}$$

and the Dirichlet random vector ($\rightarrow$ Definition II/4.4.1)

$$r = (r_1, \ldots, r_k) = \left(\frac{q_1}{q_s}, \ldots, \frac{q_k}{q_s}\right) \sim \mathrm{Dir}(\alpha_1, \ldots, \alpha_k) \; . \tag{17}$$

Obviously, it holds that

$$r_i > r_j \iff q_i > q_j \quad \text{for} \quad i, j = 1, \ldots, k \quad \text{with} \quad j \neq i \; . \tag{18}$$

Therefore, consider the probability that q_i is larger than q_j, given q_i is known. This probability is equal to the probability that q_j is smaller than q_i, given q_i is known

$$p(q_i > q_j|q_i) = p(q_j < q_i|q_i) \tag{19}$$

which can be expressed in terms of the cumulative distribution function of the gamma distribution ($\rightarrow$ Proof II/3.4.6) as

$$p(q_j < q_i|q_i) = \int_0^{q_i} \mathrm{Gam}(q_j; \alpha_j, 1) \, \mathrm{d}q_j = \frac{\gamma(\alpha_j, q_i)}{\Gamma(\alpha_j)} \tag{20}$$

where $\Gamma(x)$ is the gamma function and $\gamma(s, x)$ is the lower incomplete gamma function. Since the gamma variates are independent of each other, these probabilties factorize:

$$p(\forall_{j \neq i} [q_i > q_j] | q_i) = \prod_{j \neq i} p(q_i > q_j|q_i) = \prod_{j \neq i} \frac{\gamma(\alpha_j, q_i)}{\Gamma(\alpha_j)} \, . \tag{21}$$

In order to obtain the exceedance probability φ_i, the dependency on q_i in this probability still has to be removed. From equations (**??**) and (**??**), it follows that

$$\varphi_i = p(\forall_{j \neq i} [r_i > r_j]) = p(\forall_{j \neq i} [q_i > q_j]) \, . \tag{22}$$

Using the law of marginal probability ($\rightarrow$ Definition I/1.2.3), we have

$$\varphi_i = \int_0^\infty p(\forall_{j \neq i} [q_i > q_j] | q_i) \, p(q_i) \, \mathrm{d}q_i \, . \tag{23}$$

With (**??**) and (**??**), this becomes

$$\varphi_i = \int_0^\infty \prod_{j \neq i} (p(q_i > q_j|q_i)) \cdot \mathrm{Gam}(q_i; \alpha_i, 1) \, \mathrm{d}q_i \, . \tag{24}$$

And with (**??**) and (**??**), it becomes

$$\varphi_i = \int_0^\infty \prod_{j \neq i} \left(\frac{\gamma(\alpha_j, q_i)}{\Gamma(\alpha_j)} \right) \cdot \frac{q_i^{\alpha_i - 1} \exp[-q_i]}{\Gamma(\alpha_i)} \, \mathrm{d}q_i \, . \tag{25}$$

In other words, the exceedance probability ($\rightarrow$ Definition I/1.2.5) for one element from a Dirichlet-distributed ($\rightarrow$ Definition II/4.4.1) random vector ($\rightarrow$ Definition I/1.1.4) is an integral from zero to infinity where the first term in the integrand conforms to a product of gamma ($\rightarrow$ Definition II/3.4.1) cumulative distribution functions ($\rightarrow$ Definition I/1.4.8) and the second term is a gamma ($\rightarrow$ Definition II/3.4.1) probability density function ($\rightarrow$ Definition I/1.4.4).

5.1.3 Equivalence to multivariate normal distribution

Theorem: The matrix X is matrix-normally distributed ($\to$ Definition II/5.1.1)

$$X \sim \mathcal{MN}(M, U, V), \tag{1}$$

if and only if $\mathrm{vec}(X)$ is multivariate normally distributed ($\to$ Definition II/4.1.1)

$$\mathrm{vec}(X) \sim \mathcal{MN}(\mathrm{vec}(M), V \otimes U) \tag{2}$$

where $\mathrm{vec}(X)$ is the vectorization operator and $\otimes$ is the Kronecker product.

Proof: The probability density function of the matrix-normal distribution ($\to$ Proof II/5.1.2) with $n \times p$ mean M, $n \times n$ covariance across rows U and $p \times p$ covariance across columns V is

$$\mathcal{MN}(X; M, U, V) = \frac{1}{\sqrt{(2\pi)^{np}|V|^n|U|^p}} \cdot \exp\left[-\frac{1}{2}\mathrm{tr}\left(V^{-1}(X-M)^\mathrm{T}\,U^{-1}(X-M)\right)\right]. \tag{3}$$

Using the trace property $\mathrm{tr}(ABC) = \mathrm{tr}(BCA)$, we have:

$$\mathcal{MN}(X; M, U, V) = \frac{1}{\sqrt{(2\pi)^{np}|V|^n|U|^p}} \cdot \exp\left[-\frac{1}{2}\mathrm{tr}\left((X-M)^\mathrm{T}\,U^{-1}(X-M)\,V^{-1}\right)\right]. \tag{4}$$

Using the trace-vectorization relation $\mathrm{tr}(A^\mathrm{T}B) = \mathrm{vec}(A)^\mathrm{T}\,\mathrm{vec}(B)$, we have:

$$\mathcal{MN}(X; M, U, V) = \frac{1}{\sqrt{(2\pi)^{np}|V|^n|U|^p}} \cdot \exp\left[-\frac{1}{2}\mathrm{vec}(X-M)^\mathrm{T}\,\mathrm{vec}\left(U^{-1}(X-M)\,V^{-1}\right)\right]. \tag{5}$$

Using the vectorization-Kronecker relation $\mathrm{vec}(ABC) = \left(C^\mathrm{T} \otimes A\right)\mathrm{vec}(B)$, we have:

$$\mathcal{MN}(X; M, U, V) = \frac{1}{\sqrt{(2\pi)^{np}|V|^n|U|^p}} \cdot \exp\left[-\frac{1}{2}\mathrm{vec}(X-M)^\mathrm{T}\,\left(V^{-1} \otimes U^{-1}\right)\mathrm{vec}(X-M)\right]. \tag{6}$$

Using the Kronecker product property $\left(A^{-1} \otimes B^{-1}\right) = (A \otimes B)^{-1}$, we have:

$$\mathcal{MN}(X; M, U, V) = \frac{1}{\sqrt{(2\pi)^{np}|V|^n|U|^p}} \cdot \exp\left[-\frac{1}{2}\mathrm{vec}(X-M)^\mathrm{T}\,(V \otimes U)^{-1}\,\mathrm{vec}(X-M)\right]. \tag{7}$$

Using the vectorization property $\mathrm{vec}(A+B) = \mathrm{vec}(A) + \mathrm{vec}(B)$, we have:

$$\mathcal{MN}(X; M, U, V) = \frac{1}{\sqrt{(2\pi)^{np}|V|^n|U|^p}} \cdot \exp\left[-\frac{1}{2}\left[\mathrm{vec}(X) - \mathrm{vec}(M)\right]^\mathrm{T}\,(V \otimes U)^{-1}\left[\mathrm{vec}(X) - \mathrm{vec}(M)\right]\right]. \tag{8}$$

Using the Kronecker-determinant relation $|A \otimes B| = |A|^m|B|^n$, we have:

$$\mathcal{MN}(X; M, U, V) = \frac{1}{\sqrt{(2\pi)^{np}|V \otimes U|}} \cdot \exp\left[-\frac{1}{2}\left[\mathrm{vec}(X) - \mathrm{vec}(M)\right]^\mathrm{T}\,(V \otimes U)^{-1}\left[\mathrm{vec}(X) - \mathrm{vec}(M)\right]\right]. \tag{9}$$

This is the probability density function of the multivariate normal distribution ($\rightarrow$ Proof II/4.1.2) with the $np \times 1$ mean vector $\text{vec}(M)$ and the $np \times np$ covariance matrix $V \otimes U$:

$$\mathcal{MN}(X; M, U, V) = \mathcal{N}(\text{vec}(X); \text{vec}(M), V \otimes U) \ . \tag{10}$$

By showing that the probability density functions ($\rightarrow$ Definition I/1.4.4) are identical, it is proven that the associated probability distributions ($\rightarrow$ Definition I/1.3.1) are equivalent.

5.1.4 Transposition

Theorem: Let X be a random matrix ($\rightarrow$ Definition I/1.1.5) following a matrix-normal distribution ($\rightarrow$ Definition II/5.1.1):

$$X \sim \mathcal{MN}(M, U, V) \ . \tag{1}$$

Then, the transpose of X also has a matrix-normal distribution:

$$X^{\mathrm{T}} \sim \mathcal{MN}(M^{\mathrm{T}}, V, U) \ . \tag{2}$$

Proof: The probability density function of the matrix-normal distribution ($\rightarrow$ Proof II/5.1.2) is:

$$f(X) = \mathcal{MN}(X; M, U, V) = \frac{1}{\sqrt{(2\pi)^{np} |V|^n |U|^p}} \cdot \exp\left[-\frac{1}{2} \text{tr}\left(V^{-1}(X - M)^{\mathrm{T}} U^{-1}(X - M) \right) \right] \ . \tag{3}$$

Define $Y = X^{\mathrm{T}}$. Then, $X = Y^{\mathrm{T}}$ and we can substitute:

$$f(Y) = \frac{1}{\sqrt{(2\pi)^{np} |V|^n |U|^p}} \cdot \exp\left[-\frac{1}{2} \text{tr}\left(V^{-1}(Y^{\mathrm{T}} - M)^{\mathrm{T}} U^{-1}(Y^{\mathrm{T}} - M) \right) \right] \ . \tag{4}$$

Using $(A + B)^{\mathrm{T}} = (A^{\mathrm{T}} + B^{\mathrm{T}})$, we have:

$$f(Y) = \frac{1}{\sqrt{(2\pi)^{np} |V|^n |U|^p}} \cdot \exp\left[-\frac{1}{2} \text{tr}\left(V^{-1}(Y - M^{\mathrm{T}}) U^{-1}(Y - M^{\mathrm{T}})^{\mathrm{T}} \right) \right] \ . \tag{5}$$

Using $\text{tr}(ABC) = \text{tr}(CAB)$, we obtain

$$f(Y) = \frac{1}{\sqrt{(2\pi)^{np} |V|^n |U|^p}} \cdot \exp\left[-\frac{1}{2} \text{tr}\left(U^{-1}(Y - M^{\mathrm{T}})^{\mathrm{T}} V^{-1}(Y - M^{\mathrm{T}}) \right) \right] \tag{6}$$

which is the probability density function of a matrix-normal distribution ($\rightarrow$ Proof II/5.1.2) with mean M^T, covariance across rows V and covariance across columns U.

5.1.5 Linear transformation

Theorem: Let X be an $n \times p$ random matrix ($\rightarrow$ Definition I/1.1.5) following a matrix-normal distribution ($\rightarrow$ Definition II/5.1.1):

$$X \sim \mathcal{MN}(M, U, V) \, . \tag{1}$$

Then, a linear transformation of X is also matrix-normally distributed

$$Y = AXB + C \sim \mathcal{MN}(AMB + C, AUA^{\mathrm{T}}, B^{\mathrm{T}}VB) \tag{2}$$

where A us ab $r \times n$ matrix of full rank $r \leq b$ and B is a $p \times s$ matrix of full rank $s \leq p$ and C is an $r \times s$ matrix.

Proof: The matrix-normal distribution is equivalent to the multivariate normal distribution ($\rightarrow$ Proof II/5.1.3),

$$X \sim \mathcal{MN}(M, U, V) \quad \Leftrightarrow \quad \mathrm{vec}(X) \sim \mathcal{N}(\mathrm{vec}(M), V \otimes U) \, , \tag{3}$$

and the linear transformation theorem for the multivariate normal distribution ($\rightarrow$ Proof II/4.1.5) states:

$$x \sim \mathcal{N}(\mu, \Sigma) \quad \Rightarrow \quad y = Ax + b \sim \mathcal{N}(A\mu + b, A\Sigma A^{\mathrm{T}}) \, . \tag{4}$$

The vectorization of $Y = AXB + C$ is

$$\begin{aligned}
\mathrm{vec}(Y) &= \mathrm{vec}(AXB + C) \\
&= \mathrm{vec}(AXB) + \mathrm{vec}(C) \\
&= (B^{\mathrm{T}} \otimes A)\mathrm{vec}(X) + \mathrm{vec}(C) \, .
\end{aligned} \tag{5}$$

Using (3) and (4), we have

$$\begin{aligned}
\mathrm{vec}(Y) &\sim \mathcal{N}((B^{\mathrm{T}} \otimes A)\mathrm{vec}(M) + \mathrm{vec}(C), (B^{\mathrm{T}} \otimes A)(V \otimes U)(B^{\mathrm{T}} \otimes A)^{\mathrm{T}}) \\
&= \mathcal{N}(\mathrm{vec}(AMB) + \mathrm{vec}(C), (B^{\mathrm{T}}V \otimes AU)(B^{\mathrm{T}} \otimes A)^{\mathrm{T}}) \\
&= \mathcal{N}(\mathrm{vec}(AMB + C), B^{\mathrm{T}}VB \otimes AUA^{\mathrm{T}}) \, .
\end{aligned} \tag{6}$$

Using (3), we finally have:

$$Y \sim \mathcal{MN}(AMB + C, AUA^{\mathrm{T}}, B^{\mathrm{T}}VB) \, . \tag{7}$$

5.2   Wishart distribution

5.2.1   Definition

Definition: Let X be an $n \times p$ matrix following a matrix-normal distribution ($\rightarrow$ Definition II/5.1.1) with mean zero, independence across rows and covariance across columns V:

$$X \sim \mathcal{MN}(0, I_n, V) \ . \tag{1}$$

Define the scatter matrix S as the product of the transpose of X with itself:

$$S = X^T X = \sum_{i=1}^{n} x_i^{\mathrm{T}} x_i \ . \tag{2}$$

Then, the matrix S is said to follow a Wishart distribution with scale matrix V and degrees of freedom n

$$S \sim \mathcal{W}(V, n) \tag{3}$$

where $n > p - 1$ and V is a positive definite symmetric covariance matrix.

Chapter III

Statistical Models

1 Univariate normal data

1.1 Univariate Gaussian

1.1.1 Definition

Definition: A univariate Gaussian data set is given by a set of real numbers $y = \{y_1, \ldots, y_n\}$, independent and identically distributed according to a normal distribution ($\rightarrow$ Definition II/3.2.1) with unknown mean μ and unknown variance σ^2:

$$y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \ . \tag{1}$$

Sources:
- Bishop, Christopher M. (2006): "Example: The univariate Gaussian"; in: *Pattern Recognition for Machine Learning*, ch. 10.1.3, p. 470, eq. 10.21; URL: http://users.isr.ist.utl.pt/~wurmd/Livros/school/Bishop%20-%20Pattern%20Recognition%20And%20Machine%20Learning%20-%20Springer%20%202006.pdf.

1.1.2 Maximum likelihood estimation

Theorem: Let there be a univariate Gaussian data set ($\rightarrow$ Definition III/1.1.1) $y = \{y_1, \ldots, y_n\}$:

$$y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \ . \tag{1}$$

Then, the maximum likelihood estimates ($\rightarrow$ Definition I/4.1.3) for mean μ and variance σ^2 are given by

$$
\begin{aligned}
\hat{\mu} &= \frac{1}{n} \sum_{i=1}^{n} y_i \\
\hat{\sigma}^2 &= \frac{1}{n} \sum_{i=1}^{n} (y_i - \bar{y})^2 \ .
\end{aligned}
\tag{2}
$$

Proof: The likelihood function ($\rightarrow$ Definition I/5.1.2) for each observation is given by the probability density function of the normal distribution ($\rightarrow$ Proof II/3.2.7)

$$p(y_i|\mu, \sigma^2) = \mathcal{N}(x; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} \cdot \exp\left[-\frac{1}{2} \left(\frac{y_i - \mu}{\sigma} \right)^2 \right] \tag{3}$$

and because observations are independent ($\rightarrow$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$p(y|\mu, \sigma^2) = \prod_{i=1}^{n} p(y_i|\mu) = \sqrt{\frac{1}{(2\pi\sigma^2)^n}} \cdot \exp\left[-\frac{1}{2} \sum_{i=1}^{n} \left(\frac{y_i - \mu}{\sigma} \right)^2 \right] \ . \tag{4}$$

This can be developed into

$$p(y|\mu, \sigma^2) = \left(\frac{1}{2\pi\sigma^2} \right)^{n/2} \cdot \exp\left[-\frac{1}{2} \sum_{i=1}^{n} \left(\frac{y_i^2 - 2y_i\mu + \mu^2}{\sigma^2} \right) \right]$$

$$= \left(\frac{1}{2\pi\sigma^2} \right)^{n/2} \cdot \exp\left[-\frac{1}{2\sigma^2} \left(y^\mathrm{T}y - 2n\bar{y}\mu + n\mu^2 \right) \right] \tag{5}$$

where $\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i$ is the mean of data points and $y^\mathrm{T}y = \sum_{i=1}^{n} y_i^2$ is the sum of squared data points. Thus, the log-likelihood function ($\rightarrow$ Definition I/4.1.2) is

$$\mathrm{LL}(\mu, \sigma^2) = \log p(y|\mu, \sigma^2) = -\frac{n}{2}\log(2\pi\sigma^2) - \frac{1}{2\sigma^2}\left(y^\mathrm{T}y - 2n\bar{y}\mu + n\mu^2 \right) \ . \tag{6}$$

The derivative of the log-likelihood function (6) with respect to μ is

$$\frac{\mathrm{dLL}(\mu, \sigma^2)}{\mathrm{d}\mu} = \frac{n\bar{y}}{\sigma^2} - \frac{n\mu}{\sigma^2} = \frac{n}{\sigma^2}(\bar{y} - \mu) \tag{7}$$

and setting this derivative to zero gives the MLE for μ:

$$\frac{\mathrm{dLL}(\hat{\mu}, \sigma^2)}{\mathrm{d}\mu} = 0$$
$$0 = \frac{n}{\sigma^2}(\bar{y} - \hat{\mu})$$
$$0 = \bar{y} - \hat{\mu} \tag{8}$$
$$\hat{\mu} = \bar{y}$$
$$\hat{\mu} = \frac{1}{n} \sum_{i=1}^{n} y_i \ .$$

The derivative of the log-likelihood function (6) at $\hat{\mu}$ with respect to σ^2 is

$$\frac{\mathrm{dLL}(\hat{\mu}, \sigma^2)}{\mathrm{d}\sigma^2} = -\frac{n}{2}\frac{1}{\sigma^2} + \frac{1}{2(\sigma^2)^2}\left(y^\mathrm{T}y - 2n\bar{y}\hat{\mu} + n\hat{\mu}^2 \right)$$

$$= -\frac{n}{2\sigma^2} + \frac{1}{2(\sigma^2)^2} \sum_{i=1}^{n} \left(y_i^2 - 2y_i\hat{\mu} + \hat{\mu}^2 \right) \tag{9}$$

$$= -\frac{n}{2\sigma^2} + \frac{1}{2(\sigma^2)^2} \sum_{i=1}^{n} (y_i - \hat{\mu})^2$$

and setting this derivative to zero gives the MLE for σ^2:

$$\frac{\mathrm{dLL}(\hat{\mu}, \hat{\sigma}^2)}{\mathrm{d}\sigma^2} = 0$$

$$0 = \frac{1}{2(\hat{\sigma}^2)^2} \sum_{i=1}^{n}(y_i - \hat{\mu})^2$$

$$\frac{n}{2\hat{\sigma}^2} = \frac{1}{2(\hat{\sigma}^2)^2} \sum_{i=1}^{n}(y_i - \hat{\mu})^2$$

$$\frac{2(\hat{\sigma}^2)^2}{n} \cdot \frac{n}{2\hat{\sigma}^2} = \frac{2(\hat{\sigma}^2)^2}{n} \cdot \frac{1}{2(\hat{\sigma}^2)^2} \sum_{i=1}^{n}(y_i - \hat{\mu})^2 \qquad (10)$$

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^{n}(y_i - \hat{\mu})^2$$

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^{n}(y_i - \bar{y})^2$$

Together, (8) and (10) constitute the MLE for the univariate Gaussian.

1.1.3   One-sample t-test

Theorem: Let

$$y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \dots, n \qquad (1)$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.1.1) with unknown mean μ and unknown variance σ^2. Then, the test statistic ($\rightarrow$ Definition I/4.3.5)

$$t = \frac{\bar{y} - \mu_0}{s/\sqrt{n}} \qquad (2)$$

with sample mean ($\rightarrow$ Definition I/1.5.2) $\bar{y}$ and sample variance ($\rightarrow$ Definition I/1.6.2) s^2 follows a Student's t-distribution ($\rightarrow$ Definition II/3.3.1) with $n - 1$ degrees of freedom ($\rightarrow$ Definition "dof")

$$t \sim \mathrm{t}(n - 1) \qquad (3)$$

under the null hypothesis ($\rightarrow$ Definition I/4.3.2)

$$H_0 : \ \mu = \mu_0 \,. \qquad (4)$$

Proof: The sample mean ($\rightarrow$ Definition I/1.5.2) is given by

$$\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i \tag{5}$$

and the sample variance ($\rightarrow$ Definition I/1.6.2) is given by

$$s^2 = \frac{1}{n-1} \sum_{i=1}^{n} (y_i - \bar{y})^2 \ . \tag{6}$$

Using the linearity of the expected value ($\rightarrow$ Proof I/1.5.5), the additivity of the variance under independence ($\rightarrow$ Proof I/1.6.10) and scaling of the variance upon multiplication ($\rightarrow$ Proof I/1.6.7), the sample mean follows a normal distribution ($\rightarrow$ Definition II/3.2.1)

$$\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i \sim \mathcal{N}\left(\frac{1}{n}n\mu, \left(\frac{1}{n}\right)^2 n\sigma^2\right) = \mathcal{N}\left(\mu, \sigma^2/n\right) \tag{7}$$

and additionally using the invariance of the variance under addition ($\rightarrow$ Proof I/1.6.6) and applying the null hypothesis from (4), the distribution of $Z = \sqrt{n}(\bar{y} - \mu_0)/\sigma$ becomes standard normal ($\rightarrow$ Definition II/3.2.2)

$$Z = \frac{\sqrt{n}(\bar{y} - \mu_0)}{\sigma} \sim \mathcal{N}\left(\frac{\sqrt{n}}{\sigma}(\mu - \mu_0), \left(\frac{\sqrt{n}}{\sigma}\right)^2 \frac{\sigma^2}{n}\right) \overset{H_0}{=} \mathcal{N}(0, 1) \ . \tag{8}$$

Because sample variances calculated from independent normal random variables follow a chi-squared distribution ($\rightarrow$ Proof "norm-chi2"), the distribution of $V = (n-1)\,s^2/\sigma^2$ is

$$V = \frac{(n-1)\,s^2}{\sigma^2} \sim \chi^2\,(n-1) \ . \tag{9}$$

Finally, since the ratio of a standard normal random variable and a (normalized) chi-squared random variable follows a t-distribution ($\rightarrow$ Proof "norm-t"), the distribution of the test statistic ($\rightarrow$ Definition I/4.3.5) is given by

$$t = \frac{\bar{y} - \mu_0}{s/\sqrt{n}} = \frac{Z}{\sqrt{V/(n-1)}} \sim \mathrm{t}(n-1) \ . \tag{10}$$

This means that the null hypothesis ($\rightarrow$ Definition I/4.3.2) can be rejected when t is as extreme or more extreme than the critical value ($\rightarrow$ Definition I/4.3.9) obtained from the Student's t-distribution ($\rightarrow$ Definition II/3.3.1) with $n-1$ degrees of freedom ($\rightarrow$ Definition "dof") using a significance level ($\rightarrow$ Definition I/4.3.8) α.

Sources:
- Wikipedia (2021): "Student's t-distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-12; URL: https://en.wikipedia.org/wiki/Student%27s_t-distribution#Derivation.

1.1.4 Two-sample t-test

Theorem: Let

$$
\begin{aligned}
y_{1i} &\sim \mathcal{N}(\mu_1, \sigma^2), \quad i = 1, \ldots, n_1 \\
y_{2i} &\sim \mathcal{N}(\mu_2, \sigma^2), \quad i = 1, \ldots, n_2
\end{aligned}
\tag{1}
$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.1.1) representing two groups of unequal size n_1 and n_2 with unknown means μ_1 and μ_2 and equal unknown variance σ^2. Then, the test statistic ($\rightarrow$ Definition I/4.3.5)

$$
t = \frac{(\bar{y}_1 - \bar{y}_2) - \mu_\Delta}{s_p \cdot \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}
\tag{2}
$$

with sample means ($\rightarrow$ Definition I/1.5.2) $\bar{y}_1$ and $\bar{y}_2$ and pooled standard deviation ($\rightarrow$ Definition "std-pool") s_p follows a Student's t-distribution ($\rightarrow$ Definition II/3.3.1) with $n_1 + n_2 - 1$ degrees of freedom ($\rightarrow$ Definition "dof")

$$
t \sim \mathrm{t}(n_1 + n_2 - 1)
\tag{3}
$$

under the null hypothesis ($\rightarrow$ Definition I/4.3.2)

$$
H_0 : \ \mu_1 - \mu_2 = \mu_\Delta \ .
\tag{4}
$$

Proof: The sample means ($\rightarrow$ Definition I/1.5.2) are given by

$$
\begin{aligned}
\bar{y}_1 &= \frac{1}{n_1} \sum_{i=1}^{n_1} y_{1i} \\
\bar{y}_2 &= \frac{1}{n_2} \sum_{i=1}^{n_2} y_{2i}
\end{aligned}
\tag{5}
$$

and the pooled standard deviation ($\rightarrow$ Definition "std-pool") is given by

$$
s_p = \sqrt{\frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}}
\tag{6}
$$

with the sample variances ($\rightarrow$ Definition I/1.6.2)

$$
\begin{aligned}
s_1^2 &= \frac{1}{n_1 - 1} \sum_{i=1}^{n_1} (y_{1i} - \bar{y}_1)^2 \\
s_2^2 &= \frac{1}{n_2 - 1} \sum_{i=1}^{n_2} (y_{2i} - \bar{y}_2)^2 \ .
\end{aligned}
\tag{7}
$$

Using the linearity of the expected value ($\rightarrow$ Proof I/1.5.5), the additivity of the variance under independence ($\rightarrow$ Proof I/1.6.10) and scaling of the variance upon multiplication ($\rightarrow$ Proof I/1.6.7), the sample means follow a normal distribution ($\rightarrow$ Definition II/3.2.1)

$$\bar{y}_1 = \frac{1}{n_1} \sum_{i=1}^{n_1} y_{1i} \sim \mathcal{N}\left(\frac{1}{n_1} n_1 \mu_1, \left(\frac{1}{n_1}\right)^2 n_1 \sigma^2\right) = \mathcal{N}\left(\mu_1, \sigma^2/n_1\right)$$

$$\bar{y}_2 = \frac{1}{n_2} \sum_{i=1}^{n_2} y_{2i} \sim \mathcal{N}\left(\frac{1}{n_2} n_2 \mu_2, \left(\frac{1}{n_2}\right)^2 n_2 \sigma^2\right) = \mathcal{N}\left(\mu_2, \sigma^2/n_2\right) \tag{8}$$

and additionally using the invariance of the variance under addition ($\rightarrow$ Proof I/1.6.6) and applying the null hypothesis from (4), the distribution of $Z = ((\bar{y}_1 - \bar{y}_2) - \mu_\Delta)/(\sigma\sqrt{1/n_1 + 1/n_2})$ becomes standard normal ($\rightarrow$ Definition II/3.2.2)

$$Z = \frac{(\bar{y}_1 - \bar{y}_2) - \mu_\Delta}{\sigma \cdot \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \sim \mathcal{N}\left(\frac{(\mu_1 - \mu_2) - \mu_\Delta}{\sigma \cdot \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}, \left(\frac{1}{\sigma \cdot \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}\right)^2 \left(\frac{\sigma^2}{n_1} + \frac{\sigma^2}{n_2}\right)\right) \overset{H_0}{=} \mathcal{N}(0,1) \; . \tag{9}$$

Because sample variances calculated from independent normal random variables follow a chi-squared distribution ($\rightarrow$ Proof "norm-chi2"), the distribution of $V = (n_1 + n_2 - 2)\, s_p^2/\sigma^2$ is

$$V = \frac{(n_1 + n_2 - 1)\, s_p^2}{\sigma^2} \sim \chi^2\left(n_1 + n_2 - 2\right) \; . \tag{10}$$

Finally, since the ratio of a standard normal random variable and a (normalized) chi-squared random variable follows a t-distribution ($\rightarrow$ Proof "norm-t"), the distribution of the test statistic ($\rightarrow$ Definition I/4.3.5) is given by

$$t = \frac{(\bar{y}_1 - \bar{y}_2) - \mu_\Delta}{s_p \cdot \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} = \frac{Z}{\sqrt{V/(n_1 + n_2 - 2)}} \sim t(n_1 + n_2 - 2) \; . \tag{11}$$

This means that the null hypothesis ($\rightarrow$ Definition I/4.3.2) can be rejected when t is as extreme or more extreme than the critical value ($\rightarrow$ Definition I/4.3.9) obtained from the Student's t-distribution ($\rightarrow$ Definition II/3.3.1) with $n_1 + n_2 - 2$ degrees of freedom ($\rightarrow$ Definition "dof") using a significance level ($\rightarrow$ Definition I/4.3.8) α.

- Wikipedia (2021): "Student's t-test"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-12; URL: https://en.wikipedia.org/wiki/Student%27s_t-test#Equal_or_unequal_sample_sizes,_similar_variances_(1/2_%3C_sX1/sX2_%3C_2).

Metadata: ID: P205 | shortcut: ug-ttest2 | author: JoramSoch | date: 2021-03-12, 09:20.

1.1.5 Paired t-test

Theorem: Let y_{i1} and y_{i2} with $i = 1, \ldots, n$ be paired observations, such that

$$y_{i1} \sim \mathcal{N}(y_{i2} + \mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

is a univariate Gaussian data set ($\rightarrow$ Definition III/1.1.1) with unknown shift μ and unknown variance σ^2. Then, the test statistic ($\rightarrow$ Definition I/4.3.5)

$$t = \frac{\bar{d} - \mu_0}{s_d/\sqrt{n}} \quad \text{where} \quad d_i = y_{i1} - y_{i2} \tag{2}$$

with sample mean ($\rightarrow$ Definition I/1.5.2) $\bar{d}$ and sample variance ($\rightarrow$ Definition I/1.6.2) s_d^2 follows a Student's t-distribution ($\rightarrow$ Definition II/3.3.1) with $n-1$ degrees of freedom ($\rightarrow$ Definition "dof")

$$t \sim \mathrm{t}(n-1) \tag{3}$$

under the null hypothesis ($\rightarrow$ Definition I/4.3.2)

$$H_0 : \ \mu = \mu_0 \ . \tag{4}$$

Proof: Define the pair-wise difference $d_i = y_{i1} - y_{i2}$ which is, according to the linearity of the expected value ($\rightarrow$ Proof I/1.5.5) and the invariance of the variance under addition ($\rightarrow$ Proof I/1.6.6), distributed as

$$d_i = y_{i1} - y_{i2} \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \ . \tag{5}$$

Therefore, $d_1, \ldots, d_n$ satisfy the conditions of the one-sample t-test ($\rightarrow$ Proof III/1.1.3) which results in the test statistic given by (2).

Sources:
- Wikipedia (2021): "Student's t-test"; in: *Wikipedia, the free encyclopedia*, retrieved on 2021-03-12; URL: https://en.wikipedia.org/wiki/Student%27s_t-test#Dependent_t-test_for_paired_samples.

1.1.6   Conjugate prior distribution

Theorem: Let

$$y = \{y_1, \ldots, y_n\}, \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.1.1) with unknown mean μ and unknown variance σ^2. Then, the conjugate prior ($\rightarrow$ Definition I/5.2.5) for this model is a normal-gamma distribution ($\rightarrow$ Definition II/4.3.1)

$$p(\mu, \tau) = \mathcal{N}(\mu; \mu_0, (\tau \lambda_0)^{-1}) \cdot \mathrm{Gam}(\tau; a_0, b_0) \tag{2}$$

where $\tau = 1/\sigma^2$ is the inverse variance or precision.

Proof: By definition, a conjugate prior ($\rightarrow$ Definition I/5.2.5) is a prior distribution ($\rightarrow$ Definition I/5.1.3) that, when combined with the likelihood function ($\rightarrow$ Definition I/5.1.2), leads to a posterior distribution ($\rightarrow$ Definition I/5.1.7) that belongs to the same family of probability distributions ($\rightarrow$ Definition I/1.3.1). This is fulfilled when the prior density and the likelihood function are proportional to the model model parameters in the same way, i.e. the model parameters appear in the same functional form in both.

Equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$p(y|\mu, \sigma^2) = \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \sigma^2)$$

$$= \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2\right] \tag{3}$$

$$= \frac{1}{(\sqrt{2\pi\sigma^2})^n} \cdot \exp\left[-\frac{1}{2\sigma^2}\sum_{i=1}^{n}(y_i - \mu)^2\right]$$

which, for mathematical convenience, can also be parametrized as

$$p(y|\mu, \tau) = \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \tau^{-1})$$

$$= \prod_{i=1}^{n} \sqrt{\frac{\tau}{2\pi}} \cdot \exp\left[-\frac{\tau}{2}(y_i - \mu)^2\right] \tag{4}$$

$$= \left(\sqrt{\frac{\tau}{2\pi}}\right)^n \cdot \exp\left[-\frac{\tau}{2}\sum_{i=1}^{n}(y_i - \mu)^2\right]$$

using the inverse variance or precision $\tau = 1/\sigma^2$.

Seperating constant and variable terms, we have:

$$p(y|\mu, \tau) = \sqrt{\frac{1}{(2\pi)^n}} \cdot \tau^{n/2} \cdot \exp\left[-\frac{\tau}{2}\sum_{i=1}^{n}(y_i - \mu)^2\right] . \tag{5}$$

Expanding the product in the exponent, we have

$$\begin{aligned}p(y|\mu, \tau) &= \sqrt{\frac{1}{(2\pi)^n}} \cdot \tau^{n/2} \cdot \exp\left[-\frac{\tau}{2}\sum_{i=1}^{n}(y_i^2 - 2\mu y_i + \mu^2)\right] \\ &= \sqrt{\frac{1}{(2\pi)^n}} \cdot \tau^{n/2} \cdot \exp\left[-\frac{\tau}{2}\left(\sum_{i=1}^{n}y_i^2 - 2\mu\sum_{i=1}^{n}y_i + n\mu^2\right)\right] \\ &= \sqrt{\frac{1}{(2\pi)^n}} \cdot \tau^{n/2} \cdot \exp\left[-\frac{\tau}{2}\left(y^\mathrm{T}y - 2\mu n\bar{y} + n\mu^2\right)\right] \\ &= \sqrt{\frac{1}{(2\pi)^n}} \cdot \tau^{n/2} \cdot \exp\left[-\frac{\tau n}{2}\left(\frac{1}{n}y^\mathrm{T}y - 2\mu\bar{y} + \mu^2\right)\right]\end{aligned} \tag{6}$$

where $\bar{y} = \frac{1}{n}\sum_{i=1}^{n} y_i$ is the mean of data points and $y^\mathrm{T}y = \sum_{i=1}^{n} y_i^2$ is the sum of squared data points. Completing the square over μ, finally gives

$$p(y|\mu, \tau) = \sqrt{\frac{1}{(2\pi)^n}} \cdot \tau^{n/2} \cdot \exp\left[-\frac{\tau n}{2}\left((\mu - \bar{y})^2 - \bar{y}^2 + \frac{1}{n}y^\mathrm{T}y\right)\right] \tag{7}$$

In other words, the likelihood function ($\rightarrow$ Definition I/5.1.2) is proportional to a power of τ times an exponential of τ and an exponential of a squared form of μ, weighted by τ:

$$p(y|\mu,\tau) \propto \tau^{n/2} \cdot \exp\left[-\frac{\tau}{2}\left(y^{\mathrm{T}}y - n\bar{y}^2\right)\right] \cdot \exp\left[-\frac{\tau n}{2}\left(\mu - \bar{y}\right)^2\right] \; . \tag{8}$$

The same is true for a normal-gamma distribution ($\rightarrow$ Definition II/4.3.1) over μ and τ

$$p(\mu,\tau) = \mathcal{N}(\mu; \mu_0, (\tau\lambda_0)^{-1}) \cdot \mathrm{Gam}(\tau; a_0, b_0) \tag{9}$$

the probability density function of which ($\rightarrow$ Proof II/4.3.2)

$$p(\mu,\tau) = \sqrt{\frac{\tau\lambda_0}{2\pi}} \cdot \exp\left[-\frac{\tau\lambda_0}{2}\left(\mu - \mu_0\right)^2\right] \cdot \frac{b_0^{a_0}}{\Gamma(a_0)}\,\tau^{a_0-1}\exp[-b_0\tau] \tag{10}$$

exhibits the same proportionality

$$p(\mu,\tau) \propto \tau^{a_0+1/2-1} \cdot \exp[-\tau b_0] \cdot \exp\left[-\frac{\tau\lambda_0}{2}\left(\mu - \mu_0\right)^2\right] \tag{11}$$

and is therefore conjugate relative to the likelihood.

1.1.7 Posterior distribution

Theorem: Let

$$y = \{y_1,\ldots,y_n\}, \quad y_i \sim \mathcal{N}(\mu,\sigma^2), \quad i = 1,\ldots,n \tag{1}$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.1.1) with unknown mean μ and unknown variance σ^2. Moreover, assume a normal-gamma prior distribution ($\rightarrow$ Proof III/1.1.6) over the model parameters μ and $\tau = 1/\sigma^2$:

$$p(\mu,\tau) = \mathcal{N}(\mu; \mu_0, (\tau\lambda_0)^{-1}) \cdot \mathrm{Gam}(\tau; a_0, b_0) \; . \tag{2}$$

Then, the posterior distribution ($\rightarrow$ Definition I/5.1.7) is also a normal-gamma distribution ($\rightarrow$ Definition II/4.3.1)

$$p(\mu,\tau|y) = \mathcal{N}(\mu; \mu_n, (\tau\lambda_n)^{-1}) \cdot \mathrm{Gam}(\tau; a_n, b_n) \tag{3}$$

and the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$
\begin{aligned}
\mu_n &= \frac{\lambda_0 \mu_0 + n\bar{y}}{\lambda_0 + n} \\
\lambda_n &= \lambda_0 + n \\
a_n &= a_0 + \frac{n}{2} \\
b_n &= b_0 + \frac{1}{2}(y^{\mathrm{T}}y + \lambda_0 \mu_0^2 - \lambda_n \mu_n^2) \;.
\end{aligned}
\tag{4}
$$

Proof: According to Bayes' theorem ($\rightarrow$ Proof I/5.3.1), the posterior distribution ($\rightarrow$ Definition I/5.1.7) is given by

$$
p(\mu, \tau | y) = \frac{p(y|\mu, \tau)\, p(\mu, \tau)}{p(y)} \;.
\tag{5}
$$

Since $p(y)$ is just a normalization factor, the posterior is proportional ($\rightarrow$ Proof I/5.1.8) to the numerator:

$$
p(\mu, \tau | y) \propto p(y|\mu, \tau)\, p(\mu, \tau) = p(y, \mu, \tau) \;.
\tag{6}
$$

Equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$
\begin{aligned}
p(y|\mu, \sigma^2) &= \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \sigma^2) \\
&= \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma} \right)^2 \right] \\
&= \frac{1}{(\sqrt{2\pi\sigma^2})^n} \cdot \exp\left[-\frac{1}{2\sigma^2} \sum_{i=1}^{n} (y_i - \mu)^2 \right]
\end{aligned}
\tag{7}
$$

which, for mathematical convenience, can also be parametrized as

$$
\begin{aligned}
p(y|\mu, \tau) &= \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \tau^{-1}) \\
&= \prod_{i=1}^{n} \sqrt{\frac{\tau}{2\pi}} \cdot \exp\left[-\frac{\tau}{2}(y_i - \mu)^2 \right] \\
&= \left(\sqrt{\frac{\tau}{2\pi}} \right)^n \cdot \exp\left[-\frac{\tau}{2} \sum_{i=1}^{n} (y_i - \mu)^2 \right]
\end{aligned}
\tag{8}
$$

using the inverse variance or precision $\tau = 1/\sigma^2$.

Combining the likelihood function ($\rightarrow$ Definition I/5.1.2) (8) with the prior distribution ($\rightarrow$ Definition I/5.1.3) (2), the joint likelihood ($\rightarrow$ Definition I/5.1.5) of the model is given by

$$p(y, \mu, \tau) = p(y|\mu, \tau)\, p(\mu, \tau)$$

$$= \left(\sqrt{\frac{\tau}{2\pi}}\right)^n \cdot \exp\left[-\frac{\tau}{2}\sum_{i=1}^{n}(y_i - \mu)^2\right] \cdot$$

$$\sqrt{\frac{\tau\lambda_0}{2\pi}} \cdot \exp\left[-\frac{\tau\lambda_0}{2}(\mu - \mu_0)^2\right] \cdot$$

$$\frac{b_0^{a_0}}{\Gamma(a_0)}\, \tau^{a_0-1} \exp[-b_0\tau] \ . \tag{9}$$

Collecting identical variables gives:

$$p(y, \mu, \tau) = \sqrt{\frac{\tau^{n+1}\lambda_0}{(2\pi)^{n+1}}}\, \frac{b_0^{a_0}}{\Gamma(a_0)}\, \tau^{a_0-1} \exp[-b_0\tau]\cdot$$

$$\exp\left[-\frac{\tau}{2}\left(\sum_{i=1}^{n}(y_i - \mu)^2 + \lambda_0(\mu - \mu_0)^2\right)\right] \ . \tag{10}$$

Expanding the products in the exponent ($\to$ Proof III/1.1.6) gives

$$p(y, \mu, \tau) = \sqrt{\frac{\tau^{n+1}\lambda_0}{(2\pi)^{n+1}}}\, \frac{b_0^{a_0}}{\Gamma(a_0)}\, \tau^{a_0-1} \exp[-b_0\tau]\cdot$$

$$\exp\left[-\frac{\tau}{2}\left((y^{\mathrm{T}}y - 2\mu n\bar{y} + n\mu^2) + \lambda_0(\mu^2 - 2\mu\mu_0 + \mu_0^2)\right)\right] \tag{11}$$

where $\bar{y} = \frac{1}{n}\sum_{i=1}^{n} y_i$ and $y^{\mathrm{T}}y = \sum_{i=1}^{n} y_i^2$, such that

$$p(y, \mu, \tau) = \sqrt{\frac{\tau^{n+1}\lambda_0}{(2\pi)^{n+1}}}\, \frac{b_0^{a_0}}{\Gamma(a_0)}\, \tau^{a_0-1} \exp[-b_0\tau]\cdot$$

$$\exp\left[-\frac{\tau}{2}\left(\mu^2(\lambda_0 + n) - 2\mu(\lambda_0\mu_0 + n\bar{y}) + (y^{\mathrm{T}}y + \lambda_0\mu_0^2)\right)\right] \tag{12}$$

Completing the square over μ, we finally have

$$p(y, \mu, \tau) = \sqrt{\frac{\tau^{n+1}\lambda_0}{(2\pi)^{n+1}}}\, \frac{b_0^{a_0}}{\Gamma(a_0)}\, \tau^{a_0-1} \exp[-b_0\tau]\cdot$$

$$\exp\left[-\frac{\tau\lambda_n}{2}(\mu - \mu_n)^2 - \frac{\tau}{2}\left(y^{\mathrm{T}}y + \lambda_0\mu_0^2 - \lambda_n\mu_n^2\right)\right] \tag{13}$$

with the posterior hyperparameters ($\to$ Definition I/5.1.7)

$$\mu_n = \frac{\lambda_0\mu_0 + n\bar{y}}{\lambda_0 + n}$$

$$\lambda_n = \lambda_0 + n \ . \tag{14}$$

Ergo, the joint likelihood is proportional to

$$p(y, \mu, \tau) \propto \tau^{1/2} \cdot \exp\left[-\frac{\tau \lambda_n}{2} (\mu - \mu_n)^2\right] \cdot \tau^{a_n - 1} \cdot \exp\left[-b_n \tau\right] \tag{15}$$

with the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7)

$$
\begin{aligned}
a_n &= a_0 + \frac{n}{2} \\
b_n &= b_0 + \frac{1}{2}\left(y^{\mathrm{T}} y + \lambda_0 \mu_0^2 - \lambda_n \mu_n^2\right) \ .
\end{aligned}
\tag{16}
$$

From the term in (13), we can isolate the posterior distribution over μ given τ:

$$p(\mu | \tau, y) = \mathcal{N}(\mu; \mu_n, (\tau \lambda_n)^{-1}) \ . \tag{17}$$

From the remaining term, we can isolate the posterior distribution over τ:

$$p(\tau | y) = \mathrm{Gam}(\tau; a_n, b_n) \ . \tag{18}$$

Together, (17) and (18) constitute the joint ($\rightarrow$ Definition I/1.2.2) posterior distribution ($\rightarrow$ Definition I/5.1.7) of μ and τ.

1.1.8 Log model evidence

Theorem: Let

$$m: \ y = \{y_1, \ldots, y_n\}, \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.1.1) with unknown mean μ and unknown variance σ^2. Moreover, assume a normal-gamma prior distribution ($\rightarrow$ Proof III/1.1.6) over the model parameters μ and $\tau = 1/\sigma^2$:

$$p(\mu, \tau) = \mathcal{N}(\mu; \mu_0, (\tau \lambda_0)^{-1}) \cdot \mathrm{Gam}(\tau; a_0, b_0) \ . \tag{2}$$

Then, the log model evidence ($\rightarrow$ Definition IV/3.1.1) for this model is

$$\log p(y | m) = -\frac{n}{2} \log(2\pi) + \frac{1}{2} \log \frac{\lambda_0}{\lambda_n} + \log \Gamma(a_n) - \log \Gamma(a_0) + a_0 \log b_0 - a_n \log b_n \tag{3}$$

where the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$
\begin{aligned}
\mu_n &= \frac{\lambda_0 \mu_0 + n \bar{y}}{\lambda_0 + n} \\
\lambda_n &= \lambda_0 + n \\
a_n &= a_0 + \frac{n}{2} \\
b_n &= b_0 + \frac{1}{2}(y^\mathrm{T} y + \lambda_0 \mu_0^2 - \lambda_n \mu_n^2) \ .
\end{aligned}
\tag{4}
$$

Proof: According to the law of marginal probability ($\rightarrow$ Definition I/1.2.3), the model evidence ($\rightarrow$ Definition I/5.1.9) for this model is:

$$
p(y|m) = \iint p(y|\mu, \tau) \, p(\mu, \tau) \, \mathrm{d}\mu \, \mathrm{d}\tau \ .
\tag{5}
$$

According to the law of conditional probability ($\rightarrow$ Definition I/1.2.4), the integrand is equivalent to the joint likelihood ($\rightarrow$ Definition I/5.1.5):

$$
p(y|m) = \iint p(y, \mu, \tau) \, \mathrm{d}\mu \, \mathrm{d}\tau \ .
\tag{6}
$$

Equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$
\begin{aligned}
p(y|\mu, \sigma^2) &= \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \sigma^2) \\
&= \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2\right] \\
&= \frac{1}{(\sqrt{2\pi\sigma^2})^n} \cdot \exp\left[-\frac{1}{2\sigma^2}\sum_{i=1}^{n}(y_i - \mu)^2\right]
\end{aligned}
\tag{7}
$$

which, for mathematical convenience, can also be parametrized as

$$
\begin{aligned}
p(y|\mu, \tau) &= \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \tau^{-1}) \\
&= \prod_{i=1}^{n} \sqrt{\frac{\tau}{2\pi}} \cdot \exp\left[-\frac{\tau}{2}(y_i - \mu)^2\right] \\
&= \left(\sqrt{\frac{\tau}{2\pi}}\right)^n \cdot \exp\left[-\frac{\tau}{2}\sum_{i=1}^{n}(y_i - \mu)^2\right]
\end{aligned}
\tag{8}
$$

using the inverse variance or precision $\tau = 1/\sigma^2$.

When deriving the posterior distribution ($\rightarrow$ Proof III/1.1.7) $p(\mu, \tau|y)$, the joint likelihood $p(y, \mu, \tau)$ is obtained as

$$p(y, \mu, \tau) = \sqrt{\frac{\tau^{n+1}\lambda_0}{(2\pi)^{n+1}}} \frac{b_0{}^{a_0}}{\Gamma(a_0)} \tau^{a_0-1} \exp[-b_0\tau] \cdot$$
$$\exp\left[-\frac{\tau\lambda_n}{2}(\mu - \mu_n)^2 - \frac{\tau}{2}\left(y^{\mathrm{T}}y + \lambda_0\mu_0^2 - \lambda_n\mu_n^2\right)\right] . \tag{9}$$

Using the probability density function of the normal distribution ($\rightarrow$ Proof II/3.2.7), we can rewrite this as

$$p(y, \mu, \tau) = \sqrt{\frac{\tau^n}{(2\pi)^n}} \sqrt{\frac{\tau\lambda_0}{2\pi}} \sqrt{\frac{2\pi}{\tau\lambda_n}} \frac{b_0{}^{a_0}}{\Gamma(a_0)} \tau^{a_0-1} \exp[-b_0\tau] \cdot$$
$$\mathcal{N}(\mu; \mu_n, (\tau\lambda_n)^{-1}) \exp\left[-\frac{\tau}{2}\left(y^{\mathrm{T}}y + \lambda_0\mu_0^2 - \lambda_n\mu_n^2\right)\right] . \tag{10}$$

Now, μ can be integrated out easily:

$$\int p(y, \mu, \tau) \, \mathrm{d}\mu = \sqrt{\frac{1}{(2\pi)^n}} \sqrt{\frac{\lambda_0}{\lambda_n}} \frac{b_0{}^{a_0}}{\Gamma(a_0)} \tau^{a_0+n/2-1} \exp[-b_0\tau] \cdot$$
$$\exp\left[-\frac{\tau}{2}\left(y^{\mathrm{T}}y + \lambda_0\mu_0^2 - \lambda_n\mu_n^2\right)\right] . \tag{11}$$

Using the probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5), we can rewrite this as

$$\int p(y, \mu, \tau) \, \mathrm{d}\mu = \sqrt{\frac{1}{(2\pi)^n}} \sqrt{\frac{\lambda_0}{\lambda_n}} \frac{b_0{}^{a_0}}{\Gamma(a_0)} \frac{\Gamma(a_n)}{b_n{}^{a_n}} \mathrm{Gam}(\tau; a_n, b_n) . \tag{12}$$

Finally, τ can also be integrated out:

$$\iint p(y, \mu, \tau) \, \mathrm{d}\mu \, \mathrm{d}\tau = \sqrt{\frac{1}{(2\pi)^n}} \sqrt{\frac{\lambda_0}{\lambda_n}} \frac{\Gamma(a_n)}{\Gamma(a_0)} \frac{b_0{}^{a_0}}{b_n{}^{a_n}} . \tag{13}$$

Thus, the log model evidence ($\rightarrow$ Definition IV/3.1.1) of this model is given by

$$\log p(y|m) = -\frac{n}{2}\log(2\pi) + \frac{1}{2}\log\frac{\lambda_0}{\lambda_n} + \log\Gamma(a_n) - \log\Gamma(a_0) + a_0\log b_0 - a_n\log b_n . \tag{14}$$

1.2 Univariate Gaussian with known variance

1.2.1 Definition

Definition: A univariate Gaussian data set with known variance is given by a set of real numbers $y = \{y_1, \ldots, y_n\}$, independent and identically distributed according to a normal distribution ($\rightarrow$ Definition II/3.2.1) with unknown mean μ and known variance σ^2:

$$y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \; . \tag{1}$$

Sources:
- Bishop, Christopher M. (2006): "Bayesian inference for the Gaussian"; in: *Pattern Recognition for Machine Learning*, ch. 2.3.6, p. 97, eq. 2.137; URL: http://users.isr.ist.utl.pt/~wurmd/Livros/school/Bishop%20-%20Pattern%20Recognition%20And%20Machine%20Learning%20-%20Springer%20%202006.pdf.

Metadata: ID: D136 | shortcut: ugkv | author: JoramSoch | date: 2021-03-23, 16:12.

1.2.2 Maximum likelihood estimation

Theorem: Let there be univariate Gaussian data with known variance ($\rightarrow$ Definition III/1.2.1) $y = \{y_1, \ldots, y_n\}$:

$$y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \; . \tag{1}$$

Then, the maximum likelihood estimate ($\rightarrow$ Definition I/4.1.3) for the mean μ is given by

$$\hat{\mu} = \bar{y} \tag{2}$$

where $\bar{y}$ is the sample mean ($\rightarrow$ Definition I/1.5.2)

$$\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i \; . \tag{3}$$

Proof: The likelihood function ($\rightarrow$ Definition I/5.1.2) for each observation is given by the probability density function of the normal distribution ($\rightarrow$ Proof II/3.2.7)

$$p(y_i|\mu) = \mathcal{N}(x; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} \cdot \exp\left[-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2\right] \tag{4}$$

and because observations are independent ($\rightarrow$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$p(y|\mu) = \prod_{i=1}^{n} p(y_i|\mu) = \sqrt{\frac{1}{(2\pi\sigma^2)^n}} \cdot \exp\left[-\frac{1}{2}\sum_{i=1}^{n}\left(\frac{y_i - \mu}{\sigma}\right)^2\right] \; . \tag{5}$$

This can be developed into

$$p(y|\mu) = \left(\frac{1}{2\pi\sigma^2}\right)^{n/2} \cdot \exp\left[-\frac{1}{2}\sum_{i=1}^{n}\left(\frac{y_i^2 - 2y_i\mu + \mu^2}{\sigma^2}\right)\right]$$
$$= \left(\frac{1}{2\pi\sigma^2}\right)^{n/2} \cdot \exp\left[-\frac{1}{2\sigma^2}\left(y^\mathrm{T}y - 2n\bar{y}\mu + n\mu^2\right)\right] \tag{6}$$

where $\bar{y} = \frac{1}{n}\sum_{i=1}^{n} y_i$ is the mean of data points and $y^\mathrm{T}y = \sum_{i=1}^{n} y_i^2$ is the sum of squared data points. Thus, the log-likelihood function ($\rightarrow$ Definition I/4.1.2) is

$$\mathrm{LL}(\mu) = \log p(y|\mu) = -\frac{n}{2}\log(2\pi\sigma^2) - \frac{1}{2\sigma^2}\left(y^\mathrm{T}y - 2n\bar{y}\mu + n\mu^2\right) \ . \tag{7}$$

The derivatives of the log-likelihood with respect to μ are

$$\frac{\mathrm{dLL}(\mu)}{\mathrm{d}\mu} = \frac{n\bar{y}}{\sigma^2} - \frac{n\mu}{\sigma^2} = \frac{n}{\sigma^2}(\bar{y} - \mu)$$
$$\frac{\mathrm{d}^2\mathrm{LL}(\mu)}{\mathrm{d}\mu^2} = -\frac{n}{\sigma^2} \ . \tag{8}$$

Setting the first derivative to zero, we obtain:

$$\frac{\mathrm{dLL}(\hat{\mu})}{\mathrm{d}\mu} = 0$$
$$0 = \frac{n}{\sigma^2}(\bar{y} - \hat{\mu}) \tag{9}$$
$$0 = \bar{y} - \hat{\mu}$$
$$\hat{\mu} = \bar{y}$$

Plugging this value into the second derivative, we confirm:

$$\frac{\mathrm{d}^2\mathrm{LL}(\hat{\mu})}{\mathrm{d}\mu^2} = -\frac{n}{\sigma^2} < 0 \ . \tag{10}$$

This demonstrates that the estimate $\hat{\mu} = \bar{y}$ maximizes the likelihood $p(y|\mu)$.

1.2.3 One-sample z-test

Theorem: Let

$$y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.2.1) with unknown mean μ and known variance σ^2. Then, the test statistic ($\rightarrow$ Definition I/4.3.5)

$$z = \sqrt{n}\,\frac{\bar{y} - \mu_0}{\sigma} \tag{2}$$

with sample mean ($\rightarrow$ Definition I/1.5.2) $\bar{y}$ follows a standard normal distribution ($\rightarrow$ Definition II/3.2.2)

$$z \sim \mathcal{N}(0, 1) \tag{3}$$

under the null hypothesis ($\rightarrow$ Definition I/4.3.2)

$$H_0: \ \mu = \mu_0 \ . \tag{4}$$

Proof: The sample mean ($\rightarrow$ Definition I/1.5.2) is given by

$$\bar{y} = \frac{1}{n}\sum_{i=1}^{n} y_i \ . \tag{5}$$

Using the linearity of the expected value ($\rightarrow$ Proof I/1.5.5), the additivity of the variance under independence ($\rightarrow$ Proof I/1.6.10) and scaling of the variance upon multiplication ($\rightarrow$ Proof I/1.6.7), the sample mean follows a normal distribution ($\rightarrow$ Definition II/3.2.1)

$$\bar{y} = \frac{1}{n}\sum_{i=1}^{n} y_i \sim \mathcal{N}\left(\frac{1}{n}n\mu, \left(\frac{1}{n}\right)^2 n\sigma^2\right) = \mathcal{N}\left(\mu, \sigma^2/n\right) \tag{6}$$

and additionally using the invariance of the variance under addition ($\rightarrow$ Proof I/1.6.6), the distribution of $z = \sqrt{n/\sigma^2}(\bar{y} - \mu_0)$ becomes

$$z = \sqrt{\frac{n}{\sigma^2}}(\bar{y} - \mu_0) \sim \mathcal{N}\left(\sqrt{\frac{n}{\sigma^2}}(\mu - \mu_0), \left(\sqrt{\frac{n}{\sigma^2}}\right)^2 \frac{\sigma^2}{n}\right) = \mathcal{N}\left(\sqrt{n}\,\frac{\mu - \mu_0}{\sigma}, 1\right) , \tag{7}$$

such that, under the null hypothesis in (4), we have:

$$z \sim \mathcal{N}(0, 1), \quad \text{if } \mu = \mu_0 \ . \tag{8}$$

This means that the null hypothesis ($\rightarrow$ Definition I/4.3.2) can be rejected when z is as extreme or more extreme than the critical value ($\rightarrow$ Definition I/4.3.9) obtained from the standard normal distribution ($\rightarrow$ Definition II/3.2.2) using a significance level ($\rightarrow$ Definition I/4.3.8) α.

1.2.4 Two-sample z-test

Theorem: Let

$$
\begin{aligned}
y_{1i} &\sim \mathcal{N}(\mu_1, \sigma_1^2), \quad i = 1, \ldots, n_1 \\
y_{2i} &\sim \mathcal{N}(\mu_2, \sigma_2^2), \quad i = 1, \ldots, n_2
\end{aligned}
\tag{1}
$$

be a univariate Gaussian data set ($\to$ Definition III/1.1.1) representing two groups of unequal size n_1 and n_2 with unknown means μ_1 and μ_2 and unknown variances σ_1^2 and σ_2^2. Then, the test statistic ($\to$ Definition I/4.3.5)

$$
z = \frac{(\bar{y}_1 - \bar{y}_2) - \mu_\Delta}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}}
\tag{2}
$$

with sample means ($\to$ Definition I/1.5.2) $\bar{y}_1$ and $\bar{y}_2$ follows a standard normal distribution ($\to$ Definition II/3.2.2)

$$
z \sim \mathcal{N}(0, 1)
\tag{3}
$$

under the null hypothesis ($\to$ Definition I/4.3.2)

$$
H_0 : \ \mu_1 - \mu_2 = \mu_\Delta \ .
\tag{4}
$$

Proof: The sample means ($\to$ Definition I/1.5.2) are given by

$$
\begin{aligned}
\bar{y}_1 &= \frac{1}{n_1} \sum_{i=1}^{n_1} y_{1i} \\
\bar{y}_2 &= \frac{1}{n_2} \sum_{i=1}^{n_2} y_{2i} \ .
\end{aligned}
\tag{5}
$$

Using the linearity of the expected value ($\to$ Proof I/1.5.5), the additivity of the variance under independence ($\to$ Proof I/1.6.10) and scaling of the variance upon multiplication ($\to$ Proof I/1.6.7), the sample means follow a normal distribution ($\to$ Definition II/3.2.1)

$$
\begin{aligned}
\bar{y}_1 &= \frac{1}{n_1} \sum_{i=1}^{n_1} y_{1i} \sim \mathcal{N}\left(\frac{1}{n_1} n_1 \mu_1, \left(\frac{1}{n_1}\right)^2 n_1 \sigma^2\right) = \mathcal{N}\left(\mu_1, \sigma_1^2/n_1\right) \\
\bar{y}_2 &= \frac{1}{n_2} \sum_{i=1}^{n_2} y_{2i} \sim \mathcal{N}\left(\frac{1}{n_2} n_2 \mu_2, \left(\frac{1}{n_2}\right)^2 n_2 \sigma^2\right) = \mathcal{N}\left(\mu_2, \sigma_2^2/n_2\right)
\end{aligned}
\tag{6}
$$

and additionally using the invariance of the variance under addition ($\to$ Proof I/1.6.6), the distribution of $z = [(\bar{y}_1 - \bar{y}_2) - \mu_\Delta]/\sigma_\Delta$ becomes

$$
z = \frac{(\bar{y}_1 - \bar{y}_2) - \mu_\Delta}{\sigma_\Delta} \sim \mathcal{N}\left(\frac{(\mu_1 - \mu_2) - \mu_\Delta}{\sigma_\Delta}, \left(\frac{1}{\sigma_\Delta}\right)^2 \sigma_\Delta^2\right) = \mathcal{N}\left(\frac{(\mu_1 - \mu_2) - \mu_\Delta}{\sigma_\Delta}, 1\right)
\tag{7}
$$

where σ_Δ is the pooled standard deviation ($\to$ Definition "std-pool")

$$\sigma_\Delta = \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}} \,, \tag{8}$$

such that, under the null hypothesis in (4), we have:

$$z \sim \mathcal{N}(0,1), \quad \text{if } \mu_\Delta = \mu_1 - \mu_2 \,. \tag{9}$$

This means that the null hypothesis ($\rightarrow$ Definition I/4.3.2) can be rejected when z is as extreme or more extreme than the critical value ($\rightarrow$ Definition I/4.3.9) obtained from the standard normal distribution ($\rightarrow$ Definition II/3.2.2) using a significance level ($\rightarrow$ Definition I/4.3.8) α.

1.2.5 Paired z-test

Theorem: Let y_{i1} and y_{i2} with $i = 1, \ldots, n$ be paired observations, such that

$$y_{i1} \sim \mathcal{N}(y_{i2} + \mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

is a univariate Gaussian data set ($\rightarrow$ Definition III/1.2.1) with unknown shift μ and known variance σ^2. Then, the test statistic ($\rightarrow$ Definition I/4.3.5)

$$z = \sqrt{n}\,\frac{\bar{d} - \mu_0}{\sigma} \quad \text{where} \quad d_i = y_{i1} - y_{i2} \tag{2}$$

with sample mean ($\rightarrow$ Definition I/1.5.2) $\bar{d}$ follows a standard normal distribution ($\rightarrow$ Definition II/3.2.2)

$$z \sim \mathcal{N}(0,1) \tag{3}$$

under the null hypothesis ($\rightarrow$ Definition I/4.3.2)

$$H_0: \ \mu = \mu_0 \,. \tag{4}$$

Proof: Define the pair-wise difference $d_i = y_{i1} - y_{i2}$ which is, according to the linearity of the expected value ($\rightarrow$ Proof I/1.5.5) and the invariance of the variance under addition ($\rightarrow$ Proof I/1.6.6), distributed as

$$d_i = y_{i1} - y_{i2} \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \,. \tag{5}$$

Therefore, $d_1, \ldots, d_n$ satisfy the conditions of the one-sample z-test ($\rightarrow$ Proof III/1.2.3) which results in the test statistic given by (2).

1.2.6 Conjugate prior distribution

Theorem: Let

$$y = \{y_1, \ldots, y_n\}, \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.2.1) with unknown mean μ and known variance σ^2. Then, the conjugate prior ($\rightarrow$ Definition I/5.2.5) for this model is a normal distribution ($\rightarrow$ Definition II/3.2.1)

$$p(\mu) = \mathcal{N}(\mu; \mu_0, \lambda_0^{-1}) \tag{2}$$

with prior ($\rightarrow$ Definition I/5.1.3) mean ($\rightarrow$ Definition I/1.5.1) μ_0 and prior ($\rightarrow$ Definition I/5.1.3) precision ($\rightarrow$ Definition I/1.6.11) λ_0.

Proof: By definition, a conjugate prior ($\rightarrow$ Definition I/5.2.5) is a prior distribution ($\rightarrow$ Definition I/5.1.3) that, when combined with the likelihood function ($\rightarrow$ Definition I/5.1.2), leads to a posterior distribution ($\rightarrow$ Definition I/5.1.7) that belongs to the same family of probability distributions ($\rightarrow$ Definition I/1.3.1). This is fulfilled when the prior density and the likelihood function are proportional to the model model parameters in the same way, i.e. the model parameters appear in the same functional form in both.
Equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$\begin{aligned} p(y|\mu) &= \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \sigma^2) \\ &= \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2} \left(\frac{y_i - \mu}{\sigma} \right)^2 \right] \\ &= \left(\sqrt{\frac{1}{2\pi\sigma^2}} \right)^n \cdot \exp\left[-\frac{1}{2\sigma^2} \sum_{i=1}^{n} (y_i - \mu)^2 \right] \end{aligned} \tag{3}$$

which, for mathematical convenience, can also be parametrized as

$$\begin{aligned} p(y|\mu) &= \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \tau^{-1}) \\ &= \prod_{i=1}^{n} \sqrt{\frac{\tau}{2\pi}} \cdot \exp\left[-\frac{\tau}{2} (y_i - \mu)^2 \right] \\ &= \left(\sqrt{\frac{\tau}{2\pi}} \right)^n \cdot \exp\left[-\frac{\tau}{2} \sum_{i=1}^{n} (y_i - \mu)^2 \right] \end{aligned} \tag{4}$$

using the inverse variance or precision $\tau = 1/\sigma^2$.

Expanding the product in the exponent, we have

$$
\begin{aligned}
p(y|\mu) &= \left(\frac{\tau}{2\pi}\right)^{n/2} \cdot \exp\left[-\frac{\tau}{2}\sum_{i=1}^{n}\left(y_i^2 - 2\mu y_i + \mu^2\right)\right] \\
&= \left(\frac{\tau}{2\pi}\right)^{n/2} \cdot \exp\left[-\frac{\tau}{2}\left(\sum_{i=1}^{n}y_i^2 - 2\mu\sum_{i=1}^{n}y_i + n\mu^2\right)\right] \\
&= \left(\frac{\tau}{2\pi}\right)^{n/2} \cdot \exp\left[-\frac{\tau}{2}\left(y^{\mathrm{T}}y - 2\mu n\bar{y} + n\mu^2\right)\right] \\
&= \left(\frac{\tau}{2\pi}\right)^{n/2} \cdot \exp\left[-\frac{\tau n}{2}\left(\frac{1}{n}y^{\mathrm{T}}y - 2\mu\bar{y} + \mu^2\right)\right]
\end{aligned}
\tag{5}
$$

where $\bar{y} = \frac{1}{n}\sum_{i=1}^{n}y_i$ is the mean of data points and $y^{\mathrm{T}}y = \sum_{i=1}^{n}y_i^2$ is the sum of squared data points. Completing the square over μ, finally gives

$$
p(y|\mu) = \left(\frac{\tau}{2\pi}\right)^{n/2} \cdot \exp\left[-\frac{\tau n}{2}\left((\mu - \bar{y})^2 - \bar{y}^2 + \frac{1}{n}y^{\mathrm{T}}y\right)\right]
\tag{6}
$$

In other words, the likelihood function ($\to$ Definition I/5.1.2) is proportional to an exponential of a squared form of μ, weighted by some constant:

$$
p(y|\mu) \propto \exp\left[-\frac{\tau n}{2}(\mu - \bar{y})^2\right] \ .
\tag{7}
$$

The same is true for a normal distribution ($\to$ Definition II/3.2.1) over μ

$$
p(\mu) = \mathcal{N}(\mu; \mu_0, \lambda_0^{-1})
\tag{8}
$$

the probability density function of which ($\to$ Proof II/3.2.7)

$$
p(\mu) = \sqrt{\frac{\lambda_0}{2\pi}} \cdot \exp\left[-\frac{\lambda_0}{2}(\mu - \mu_0)^2\right]
\tag{9}
$$

exhibits the same proportionality

$$
p(\mu) \propto \exp\left[-\frac{\lambda_0}{2}(\mu - \mu_0)^2\right]
\tag{10}
$$

and is therefore conjugate relative to the likelihood.

1.2.7 Posterior distribution

Theorem: Let

$$y = \{y_1, \ldots, y_n\}, \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.2.1) with unknown mean μ and known variance σ^2. Moreover, assume a normal distribution ($\rightarrow$ Proof III/1.2.6) over the model parameter μ:

$$p(\mu) = \mathcal{N}(\mu; \mu_0, \lambda_0^{-1}) \ . \tag{2}$$

Then, the posterior distribution ($\rightarrow$ Definition I/5.1.7) is also a normal distribution ($\rightarrow$ Definition II/3.2.1)

$$p(\mu|y) = \mathcal{N}(\mu; \mu_n, \lambda_n^{-1}) \tag{3}$$

and the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$\begin{aligned}
\mu_n &= \frac{\lambda_0 \mu_0 + \tau n \bar{y}}{\lambda_0 + \tau n} \\
\lambda_n &= \lambda_0 + \tau n
\end{aligned} \tag{4}$$

with the sample mean ($\rightarrow$ Definition I/1.5.2) $\bar{y}$ and the inverse variance or precision ($\rightarrow$ Definition I/1.6.11) $\tau = 1/\sigma^2$.

Proof: According to Bayes' theorem ($\rightarrow$ Proof I/5.3.1), the posterior distribution ($\rightarrow$ Definition I/5.1.7) is given by

$$p(\mu|y) = \frac{p(y|\mu) \, p(\mu)}{p(y)} \ . \tag{5}$$

Since $p(y)$ is just a normalization factor, the posterior is proportional ($\rightarrow$ Proof I/5.1.8) to the numerator:

$$p(\mu|y) \propto p(y|\mu) \, p(\mu) = p(y, \mu) \ . \tag{6}$$

Equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$\begin{aligned}
p(y|\mu) &= \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \sigma^2) \\
&= \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma}\right)^2\right] \\
&= \left(\sqrt{\frac{1}{2\pi\sigma^2}}\right)^n \cdot \exp\left[-\frac{1}{2\sigma^2}\sum_{i=1}^{n}(y_i - \mu)^2\right]
\end{aligned} \tag{7}$$

which, for mathematical convenience, can also be parametrized as

$$p(y|\mu) = \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \tau^{-1})$$
$$= \prod_{i=1}^{n} \sqrt{\frac{\tau}{2\pi}} \cdot \exp\left[-\frac{\tau}{2}(y_i - \mu)^2\right] \tag{8}$$
$$= \left(\sqrt{\frac{\tau}{2\pi}}\right)^n \cdot \exp\left[-\frac{\tau}{2}\sum_{i=1}^{n}(y_i - \mu)^2\right]$$

using the inverse variance or precision $\tau = 1/\sigma^2$.

Combining the likelihood function ($\rightarrow$ Definition I/5.1.2) (8) with the prior distribution ($\rightarrow$ Definition I/5.1.3) (2), the joint likelihood ($\rightarrow$ Definition I/5.1.5) of the model is given by

$$p(y, \mu) = p(y|\mu)\, p(\mu)$$
$$= \left(\sqrt{\frac{\tau}{2\pi}}\right)^n \cdot \exp\left[-\frac{\tau}{2}\sum_{i=1}^{n}(y_i - \mu)^2\right] \cdot \sqrt{\frac{\lambda_0}{2\pi}} \cdot \exp\left[-\frac{\lambda_0}{2}(\mu - \mu_0)^2\right] . \tag{9}$$

Rearranging the terms, we then have:

$$p(y, \mu) = \left(\frac{\tau}{2\pi}\right)^{n/2} \cdot \sqrt{\frac{\lambda_0}{2\pi}} \cdot \exp\left[-\frac{\tau}{2}\sum_{i=1}^{n}(y_i - \mu)^2 - \frac{\lambda_0}{2}(\mu - \mu_0)^2\right] . \tag{10}$$

Expanding the products in the exponent ($\rightarrow$ Proof III/1.2.6) gives

$$p(y, \mu) = \left(\frac{\tau}{2\pi}\right)^{\frac{n}{2}} \cdot \left(\frac{\lambda_0}{2\pi}\right)^{\frac{1}{2}} \cdot \exp\left[-\frac{1}{2}\left(\sum_{i=1}^{n}\tau(y_i - \mu)^2 + \lambda_0(\mu - \mu_0)^2\right)\right]$$
$$= \left(\frac{\tau}{2\pi}\right)^{\frac{n}{2}} \cdot \left(\frac{\lambda_0}{2\pi}\right)^{\frac{1}{2}} \cdot \exp\left[-\frac{1}{2}\left(\sum_{i=1}^{n}\tau(y_i^2 - 2y_i\mu + \mu^2) + \lambda_0(\mu^2 - 2\mu\mu_0 + \mu_0^2)\right)\right]$$
$$= \left(\frac{\tau}{2\pi}\right)^{\frac{n}{2}} \cdot \left(\frac{\lambda_0}{2\pi}\right)^{\frac{1}{2}} \cdot \exp\left[-\frac{1}{2}\left(\tau(y^{\mathrm{T}}y - 2n\bar{y}\mu + n\mu^2) + \lambda_0(\mu^2 - 2\mu\mu_0 + \mu_0^2)\right)\right] \tag{11}$$
$$= \left(\frac{\tau}{2\pi}\right)^{\frac{n}{2}} \cdot \left(\frac{\lambda_0}{2\pi}\right)^{\frac{1}{2}} \cdot \exp\left[-\frac{1}{2}\left(\mu^2(\tau n + \lambda_0) - 2\mu(\tau n\bar{y} + \lambda_0\mu_0) + (\tau y^{\mathrm{T}}y + \lambda_0\mu_0^2)\right)\right]$$

where $\bar{y} = \frac{1}{n}\sum_{i=1}^{n} y_i$ and $y^{\mathrm{T}}y = \sum_{i=1}^{n} y_i^2$. Completing the square in μ then yields

$$p(y, \mu) = \left(\frac{\tau}{2\pi}\right)^{\frac{n}{2}} \cdot \left(\frac{\lambda_0}{2\pi}\right)^{\frac{1}{2}} \cdot \exp\left[-\frac{\lambda_n}{2}(\mu - \mu_n)^2 + f_n\right] \tag{12}$$

with the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7)

$$\mu_n = \frac{\lambda_0\mu_0 + \tau n\bar{y}}{\lambda_0 + \tau n}$$
$$\lambda_n = \lambda_0 + \tau n \tag{13}$$

and the remaining independent term

$$f_n = -\frac{1}{2} \left(\tau y^{\mathrm{T}} y + \lambda_0 \mu_0^2 - \lambda_n \mu_n^2 \right) \ . \tag{14}$$

Ergo, the joint likelihood in (12) is proportional to

$$p(y, \mu) \propto \exp \left[-\frac{\lambda_n}{2} (\mu - \mu_n)^2 \right] \ , \tag{15}$$

such that the posterior distribution over μ is given by

$$p(\mu|y) = \mathcal{N}(\mu; \mu_n, \lambda_n^{-1}) \ . \tag{16}$$

with the posterior hyperparameters given in (13).

1.2.8 Log model evidence

Theorem: Let

$$m : \ y = \{y_1, \dots, y_n\} \ , \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \dots, n \tag{1}$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.2.1) with unknown mean μ and known variance σ^2. Moreover, assume a normal distribution ($\rightarrow$ Proof III/1.2.6) over the model parameter μ:

$$p(\mu) = \mathcal{N}(\mu; \mu_0, \lambda_0^{-1}) \ . \tag{2}$$

Then, the log model evidence ($\rightarrow$ Definition IV/3.1.1) for this model is

$$\log p(y|m) = \frac{n}{2} \log \left(\frac{\tau}{2\pi} \right) + \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) - \frac{1}{2} \left(\tau y^T y + \lambda_0 \mu_0^2 - \lambda_n \mu_n^2 \right) \ . \tag{3}$$

where the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$\begin{aligned} \mu_n &= \frac{\lambda_0 \mu_0 + \tau n \bar{y}}{\lambda_0 + \tau n} \\ \lambda_n &= \lambda_0 + \tau n \end{aligned} \tag{4}$$

with the sample mean ($\rightarrow$ Definition I/1.5.2) $\bar{y}$ and the inverse variance or precision ($\rightarrow$ Definition I/1.6.11) $\tau = 1/\sigma^2$.

Proof: According to the law of marginal probability ($\rightarrow$ Definition I/1.2.3), the model evidence ($\rightarrow$ Definition I/5.1.9) for this model is:

$$p(y|m) = \int p(y|\mu)\, p(\mu)\, \mathrm{d}\mu \; . \tag{5}$$

According to the law of conditional probability ($\to$ Definition I/1.2.4), the integrand is equivalent to the joint likelihood ($\to$ Definition I/5.1.5):

$$p(y|m) = \int p(y, \mu)\, \mathrm{d}\mu \; . \tag{6}$$

Equation (1) implies the following likelihood function ($\to$ Definition I/5.1.2)

$$
\begin{aligned}
p(y|\mu, \sigma^2) &= \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \sigma^2) \\
&= \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{y_i - \mu}{\sigma} \right)^2 \right] \\
&= \left(\sqrt{\frac{1}{2\pi\sigma^2}} \right)^n \cdot \exp\left[-\frac{1}{2\sigma^2} \sum_{i=1}^{n} (y_i - \mu)^2 \right]
\end{aligned}
\tag{7}
$$

which, for mathematical convenience, can also be parametrized as

$$
\begin{aligned}
p(y|\mu, \tau) &= \prod_{i=1}^{n} \mathcal{N}(y_i; \mu, \tau^{-1}) \\
&= \prod_{i=1}^{n} \sqrt{\frac{\tau}{2\pi}} \cdot \exp\left[-\frac{\tau}{2}(y_i - \mu)^2 \right] \\
&= \left(\sqrt{\frac{\tau}{2\pi}} \right)^n \cdot \exp\left[-\frac{\tau}{2} \sum_{i=1}^{n} (y_i - \mu)^2 \right]
\end{aligned}
\tag{8}
$$

using the inverse variance or precision $\tau = 1/\sigma^2$.

When deriving the posterior distribution ($\to$ Proof III/1.2.7) $p(\mu|y)$, the joint likelihood $p(y, \mu)$ is obtained as

$$p(y, \mu) = \left(\frac{\tau}{2\pi} \right)^{\frac{n}{2}} \cdot \sqrt{\frac{\lambda_0}{2\pi}} \cdot \exp\left[-\frac{\lambda_n}{2}(\mu - \mu_n)^2 - \frac{1}{2}\left(\tau y^{\mathrm{T}} y + \lambda_0 \mu_0^2 - \lambda_n \mu_n^2 \right) \right] \; . \tag{9}$$

Using the probability density function of the normal distribution ($\to$ Proof II/3.2.7), we can rewrite this as

$$p(y, \mu) = \left(\frac{\tau}{2\pi} \right)^{\frac{n}{2}} \cdot \sqrt{\frac{\lambda_0}{2\pi}} \cdot \sqrt{\frac{2\pi}{\lambda_n}} \cdot \mathcal{N}(\mu; \lambda_n^{-1}) \cdot \exp\left[-\frac{1}{2}\left(\tau y^{\mathrm{T}} y + \lambda_0 \mu_0^2 - \lambda_n \mu_n^2 \right) \right] \; . \tag{10}$$

Now, μ can be integrated out using the properties of the probability density function ($\to$ Definition I/1.4.4):

$$p(y|m) = \int p(y, \mu)\, \mathrm{d}\mu = \left(\frac{\tau}{2\pi} \right)^{\frac{n}{2}} \cdot \sqrt{\frac{\lambda_0}{\lambda_n}} \cdot \exp\left[-\frac{1}{2}\left(\tau y^{\mathrm{T}} y + \lambda_0 \mu_0^2 - \lambda_n \mu_n^2 \right) \right] \; . \tag{11}$$

Thus, the log model evidence ($\rightarrow$ Definition IV/3.1.1) of this model is given by

$$\log p(y|m) = \frac{n}{2} \log\left(\frac{\tau}{2\pi}\right) + \frac{1}{2} \log\left(\frac{\lambda_0}{\lambda_n}\right) - \frac{1}{2}\left(\tau y^T y + \lambda_0 \mu_0^2 - \lambda_n \mu_n^2\right) \ . \tag{12}$$

1.2.9 Accuracy and complexity

Theorem: Let

$$y = \{y_1, \ldots, y_n\}, \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.2.1) with unknown mean μ and known variance σ^2. Moreover, assume a statistical model ($\rightarrow$ Definition I/5.1.4) imposing a normal distribution ($\rightarrow$ Proof III/1.2.6) as the prior distribution ($\rightarrow$ Definition I/5.1.3) on the model parameter μ:

$$m : \ y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu \sim \mathcal{N}(\mu_0, \lambda_0^{-1}) \ . \tag{2}$$

Then, accuracy and complexity ($\rightarrow$ Proof IV/3.1.3) of this model are

$$
\begin{aligned}
\mathrm{Acc}(m) &= \frac{n}{2} \log\left(\frac{\tau}{2\pi}\right) - \frac{1}{2}\left[\tau y^{\mathrm{T}} y - 2\,\tau n \bar{y}\mu_n + \tau n \mu_n^2 + \frac{\tau n}{\lambda_n}\right] \\
\mathrm{Com}(m) &= \frac{1}{2}\left[\frac{\lambda_0}{\lambda_n} + \lambda_0(\mu_0 - \mu_n)^2 - 1 + \log\left(\frac{\lambda_0}{\lambda_n}\right)\right]
\end{aligned}
\tag{3}
$$

where μ_n and λ_n are the posterior hyperparameters for the univariate Gaussian with known variance ($\rightarrow$ Proof III/1.2.7), $\tau = 1/\sigma^2$ is the inverse variance or precision ($\rightarrow$ Definition I/1.6.11) and $\bar{y}$ is the sample mean ($\rightarrow$ Definition I/1.5.2).

Proof: Model accuracy and complexity are defined as ($\rightarrow$ Proof IV/3.1.3)

$$
\begin{aligned}
\mathrm{LME}(m) &= \mathrm{Acc}(m) - \mathrm{Com}(m) \\
\mathrm{Acc}(m) &= \langle \log p(y|\mu, m) \rangle_{p(\mu|y,m)} \\
\mathrm{Com}(m) &= \mathrm{KL}\left[p(\mu|y, m) \,||\, p(\mu|m)\right] \ .
\end{aligned}
\tag{4}
$$

The accuracy term is the expectation ($\rightarrow$ Definition I/1.5.1) of the log-likelihood function ($\rightarrow$ Definition I/4.1.2) $\log p(y|\mu)$ with respect to the posterior distribution ($\rightarrow$ Definition I/5.1.7) $p(\mu|y)$. With the log-likelihood function for the univariate Gaussian with known variance ($\rightarrow$ Proof III/1.2.2) and the posterior distribution for the univariate Gaussian with known variance ($\rightarrow$ Proof III/1.2.7), the model accuracy of m evaluates to:

$$
\begin{aligned}
\mathrm{Acc}(m) &= \langle \log p(y|\mu) \rangle_{p(\mu|y)} \\
&= \left\langle \frac{n}{2} \log \left(\frac{\tau}{2\pi} \right) - \frac{\tau}{2} \left(y^{\mathrm{T}} y - 2n\bar{y}\mu + n\mu^2 \right) \right\rangle_{\mathcal{N}(\mu_n, \lambda_n^{-1})} \\
&= \frac{n}{2} \log \left(\frac{\tau}{2\pi} \right) - \frac{1}{2} \left[\tau y^{\mathrm{T}} y - 2\tau n \bar{y}\mu_n + \tau n \mu_n^2 + \frac{\tau n}{\lambda_n} \right] \ .
\end{aligned}
\tag{5}
$$

The complexity penalty is the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) of the posterior distribution ($\rightarrow$ Definition I/5.1.7) $p(\mu|y)$ from the prior distribution ($\rightarrow$ Definition I/5.1.7) $p(\mu)$. With the prior distribution ($\rightarrow$ Proof III/1.2.6) given by (2), the posterior distribution for the univariate Gaussian with known variance ($\rightarrow$ Proof III/1.2.7) and the Kullback-Leibler divergence of the normal distribution ($\rightarrow$ Proof II/3.2.18), the model complexity of m evaluates to:

$$
\begin{aligned}
\mathrm{Com}(m) &= \mathrm{KL}\left[p(\mu|y) \,||\, p(\mu) \right] \\
&= \mathrm{KL}\left[\mathcal{N}(\mu_n, \lambda_n^{-1}) \,||\, \mathcal{N}(\mu_0, \lambda_0^{-1}) \right] \\
&= \frac{1}{2} \left[\frac{\lambda_0}{\lambda_n} + \lambda_0 (\mu_0 - \mu_n)^2 - 1 + \log \left(\frac{\lambda_0}{\lambda_n} \right) \right] \ .
\end{aligned}
\tag{6}
$$

A control calculation confirms that

$$
\mathrm{Acc}(m) - \mathrm{Com}(m) = \mathrm{LME}(m)
\tag{7}
$$

where $\mathrm{LME}(m)$ is the log model evidence for the univariate Gaussian with known variance ($\rightarrow$ Proof III/1.2.8).

1.2.10 Log Bayes factor

Theorem: Let

$$
y = \{ y_1, \ldots, y_n \}, \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n
\tag{1}
$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.2.1) with unknown mean μ and known variance σ^2. Moreover, assume two statistical models ($\rightarrow$ Definition I/5.1.4), one assuming that μ is zero (null model ($\rightarrow$ Definition I/4.3.2)), the other imposing a normal distribution ($\rightarrow$ Proof III/1.2.6) as the prior distribution ($\rightarrow$ Definition I/5.1.3) on the model parameter μ (alternative ($\rightarrow$ Definition I/4.3.3)):

$$
\begin{aligned}
m_0 &: \ y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu = 0 \\
m_1 &: \ y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu \sim \mathcal{N}(\mu_0, \lambda_0^{-1}) \ .
\end{aligned}
\tag{2}
$$

Then, the log Bayes factor ($\rightarrow$ Definition IV/3.3.1) in favor of m_1 against m_0 is

$$\text{LBF}_{10} = \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) - \frac{1}{2} \left(\lambda_0 \mu_0^2 - \lambda_n \mu_n^2 \right) \tag{3}$$

where μ_n and λ_n are the posterior hyperparameters for the univariate Gaussian with known variance ($\to$ Proof III/1.2.7) which are functions of the inverse variance or precision ($\to$ Definition I/1.6.11) $\tau = 1/\sigma^2$ and the sample mean ($\to$ Definition I/1.5.2) $\bar{y}$.

Proof: The log Bayes factor is equal to the difference of two log model evidences ($\to$ Proof IV/3.3.3):

$$\text{LBF}_{12} = \text{LME}(m_1) - \text{LME}(m_2) \; . \tag{4}$$

The LME of the alternative m_1 is equal to the log model evidence for the univariate Gaussian with known variance ($\to$ Proof III/1.2.8):

$$\text{LME}(m_1) = \frac{n}{2} \log \left(\frac{\tau}{2\pi} \right) + \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) - \frac{1}{2} \left(\tau y^{\mathrm{T}} y + \lambda_0 \mu_0^2 - \lambda_n \mu_n^2 \right) \; . \tag{5}$$

Because the null model m_0 has no free parameter, its log model evidence ($\to$ Definition IV/3.1.1) (logarithmized marginal likelihood ($\to$ Definition I/5.1.9)) is equal to the log-likelihood function for the univariate Gaussian with known variance ($\to$ Proof III/1.2.2) at the value $\mu = 0$:

$$\text{LME}(m_0) = \log p(y|\mu = 0) = \frac{n}{2} \log \left(\frac{\tau}{2\pi} \right) - \frac{1}{2} \left(\tau y^{\mathrm{T}} y \right) \; . \tag{6}$$

Subtracting the two LMEs from each other, the LBF emerges as

$$\text{LBF}_{10} = \text{LME}(m_1) - \text{LME}(m_0) = \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) - \frac{1}{2} \left(\lambda_0 \mu_0^2 - \lambda_n \mu_n^2 \right) \tag{7}$$

where the posterior hyperparameters ($\to$ Definition I/5.1.7) are given by ($\to$ Proof III/1.2.7)

$$\begin{aligned} \mu_n &= \frac{\lambda_0 \mu_0 + \tau n \bar{y}}{\lambda_0 + \tau n} \\ \lambda_n &= \lambda_0 + \tau n \end{aligned} \tag{8}$$

with the sample mean ($\to$ Definition I/1.5.2) $\bar{y}$ and the inverse variance or precision ($\to$ Definition I/1.6.11) $\tau = 1/\sigma^2$.

1.2.11 Expectation of log Bayes factor

Theorem: Let

$$y = \{y_1, \ldots, y_n\}, \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

be a univariate Gaussian data set ($\to$ Definition III/1.2.1) with unknown mean μ and known variance σ^2. Moreover, assume two statistical models ($\to$ Definition I/5.1.4), one assuming that μ is zero (null

model ($\to$ Definition I/4.3.2)), the other imposing a normal distribution ($\to$ Proof III/1.2.6) as the prior distribution ($\to$ Definition I/5.1.3) on the model parameter μ (alternative ($\to$ Definition I/4.3.3)):

$$m_0 : \ y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu = 0$$
$$m_1 : \ y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu \sim \mathcal{N}(\mu_0, \lambda_0^{-1}) \ . \tag{2}$$

Then, under the null hypothesis ($\to$ Definition I/4.3.2) that m_0 generated the data, the expectation ($\to$ Definition I/1.5.1) of the log Bayes factor ($\to$ Definition IV/3.3.1) in favor of m_1 with $\mu_0 = 0$ against m_0 is

$$\langle \mathrm{LBF}_{10} \rangle = \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) + \frac{1}{2} \left(\frac{\lambda_n - \lambda_0}{\lambda_n} \right) \tag{3}$$

where λ_n is the posterior precision for the univariate Gaussian with known variance ($\to$ Proof III/1.2.7).

Proof: The log Bayes factor for the univariate Gaussian with known variance ($\to$ Proof III/1.2.10) is

$$\mathrm{LBF}_{10} = \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) - \frac{1}{2} \left(\lambda_0 \mu_0^2 - \lambda_n \mu_n^2 \right) \tag{4}$$

where the posterior hyperparameters ($\to$ Definition I/5.1.7) are given by ($\to$ Proof III/1.2.7)

$$\mu_n = \frac{\lambda_0 \mu_0 + \tau n \bar{y}}{\lambda_0 + \tau n}$$
$$\lambda_n = \lambda_0 + \tau n \tag{5}$$

with the sample mean ($\to$ Definition I/1.5.2) $\bar{y}$ and the inverse variance or precision ($\to$ Definition I/1.6.11) $\tau = 1/\sigma^2$. Plugging μ_n from (5) into (4), we obtain:

$$\mathrm{LBF}_{10} = \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) - \frac{1}{2} \left(\lambda_0 \mu_0^2 - \lambda_n \frac{(\lambda_0 \mu_0 + \tau n \bar{y})^2}{\lambda_n^2} \right)$$
$$= \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) - \frac{1}{2} \left(\lambda_0 \mu_0^2 - \frac{1}{\lambda_n} (\lambda_0^2 \mu_0^2 - 2\tau n \lambda_0 \mu_0 \bar{y} + \tau^2 (n\bar{y})^2) \right) \tag{6}$$

Because m_1 uses a zero-mean prior distribution ($\to$ Definition I/5.1.3) with prior mean ($\to$ Definition I/1.5.1) $\mu_0 = 0$ per construction, the log Bayes factor simplifies to:

$$\mathrm{LBF}_{10} = \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) + \frac{1}{2} \left(\frac{\tau^2 (n\bar{y})^2}{\lambda_n} \right) \ . \tag{7}$$

From (1), we know that the data are distributed as $y_i \sim \mathcal{N}(\mu, \sigma^2)$, such that we can derive the expectation ($\to$ Definition I/1.5.1) of $(n\bar{y})^2$ as follows:

$$\langle (n\bar{y})^2 \rangle = \left\langle \sum_{i=1}^{n} \sum_{j=1}^{n} y_i y_j \right\rangle = \left\langle n y_i^2 + (n^2 - n)[y_i y_j]_{i \neq j} \right\rangle$$
$$= n(\mu^2 + \sigma^2) + (n^2 - n)\mu^2 \tag{8}$$
$$= n^2 \mu^2 + n\sigma^2 \ .$$

Applying this expected value ($\rightarrow$ Definition I/1.5.1) to (7), the expected LBF emerges as:

$$
\begin{aligned}
\langle \mathrm{LBF}_{10} \rangle &= \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) + \frac{1}{2} \left(\frac{\tau^2 (n^2 \mu^2 + n\sigma^2)}{\lambda_n} \right) \\
&= \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) + \frac{1}{2} \left(\frac{(\tau n \mu)^2 + \tau n}{\lambda_n} \right)
\end{aligned}
\tag{9}
$$

Under the null hypothesis ($\rightarrow$ Definition I/4.3.2) that m_0 generated the data, the unknown mean is $\mu = 0$, such that the log Bayes factor further simplifies to:

$$
\langle \mathrm{LBF}_{10} \rangle = \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) + \frac{1}{2} \left(\frac{\tau n}{\lambda_n} \right) .
\tag{10}
$$

Finally, plugging λ_n from (5) into (10), we obtain:

$$
\langle \mathrm{LBF}_{10} \rangle = \frac{1}{2} \log \left(\frac{\lambda_0}{\lambda_n} \right) + \frac{1}{2} \left(\frac{\lambda_n - \lambda_0}{\lambda_n} \right) .
\tag{11}
$$

1.2.12 Cross-validated log model evidence

Theorem: Let

$$
y = \{ y_1, \ldots, y_n \}, \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n
\tag{1}
$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.2.1) with unknown mean μ and known variance σ^2. Moreover, assume two statistical models ($\rightarrow$ Definition I/5.1.4), one assuming that μ is zero (null model ($\rightarrow$ Definition I/4.3.2)), the other imposing a normal distribution ($\rightarrow$ Proof III/1.2.6) as the prior distribution ($\rightarrow$ Definition I/5.1.3) on the model parameter μ (alternative ($\rightarrow$ Definition I/4.3.3)):

$$
\begin{aligned}
m_0 &: \ y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu = 0 \\
m_1 &: \ y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu \sim \mathcal{N}(\mu_0, \lambda_0^{-1}) .
\end{aligned}
\tag{2}
$$

Then, the cross-validated log model evidences ($\rightarrow$ Definition IV/3.1.5) of m_0 and m_1 are

$$
\begin{aligned}
\mathrm{cvLME}(m_0) &= \frac{n}{2} \log \left(\frac{\tau}{2\pi} \right) - \frac{1}{2} \left(\tau y^{\mathrm{T}} y \right) \\
\mathrm{cvLME}(m_1) &= \frac{n}{2} \log \left(\frac{\tau}{2\pi} \right) + \frac{S}{2} \log \left(\frac{S-1}{S} \right) - \frac{\tau}{2} \left[y^{\mathrm{T}} y + \sum_{i=1}^{S} \left(\frac{\left(n_1 \bar{y}_1^{(i)} \right)^2}{n_1} - \frac{(n\bar{y})^2}{n} \right) \right]
\end{aligned}
\tag{3}
$$

where $\bar{y}$ is the sample mean ($\rightarrow$ Definition I/1.5.2), $\tau = 1/\sigma^2$ is the inverse variance or precision ($\rightarrow$ Definition I/1.6.11), $y_1^{(i)}$ are the training data in the i-th cross-validation fold and S is the number of data subsets ($\rightarrow$ Definition IV/3.1.5).

Proof: For evaluation of the cross-validated log model evidences ($\to$ Definition IV/3.1.5) (cvLME), we assume that n data points are divided into $S \mid n$ data subsets without remainder. Then, the number of training data points n_1 and test data points n_2 are given by

$$
\begin{aligned}
n &= n_1 + n_2 \\
n_1 &= \frac{S-1}{S} n \\
n_2 &= \frac{1}{S} n \; ,
\end{aligned}
\tag{4}
$$

such that training data y_1 and test data y_2 in the i-th cross-validation fold are

$$
\begin{aligned}
y &= \{y_1, \dots, y_n\} \\
y_1^{(i)} &= \left\{ x \in y \mid x \notin y_2^{(i)} \right\} = y \backslash y_2^{(i)} \\
y_2^{(i)} &= \left\{ y_{(i-1) \cdot n_2 + 1}, \dots, y_{i \cdot n_2} \right\} \; .
\end{aligned}
\tag{5}
$$

First, we consider the null model m_0 assuming $\mu = 0$. Because this model has no free parameter, nothing is estimated from the training data and the assumed parameter value is applied to the test data. Consequently, the out-of-sample log model evidence ($\to$ Definition "ooslme") (oosLME) is equal to the log-likelihood function ($\to$ Proof III/1.2.2) of the test data at $\mu = 0$:

$$
\text{oosLME}_i(m_0) = \log p\left(y_2^{(i)} \,\middle|\, \mu = 0 \right) = \frac{n_2}{2} \log\left(\frac{\tau}{2\pi} \right) - \frac{1}{2} \left[\tau y_2^{(i)\mathrm{T}} y_2^{(i)} \right] \; .
\tag{6}
$$

By definition, the cross-validated log model evidence is the sum of out-of-sample log model evidences ($\to$ Definition IV/3.1.5) over cross-validation folds, such that the cvLME of m_0 is:

$$
\begin{aligned}
\text{cvLME}(m_0) &= \sum_{i=1}^{S} \text{oosLME}_i(m_0) \\
&= \sum_{i=1}^{S} \left(\frac{n_2}{2} \log\left(\frac{\tau}{2\pi} \right) - \frac{1}{2} \left[\tau y_2^{(i)\mathrm{T}} y_2^{(i)} \right] \right) \\
&= \frac{n}{2} \log\left(\frac{\tau}{2\pi} \right) - \frac{1}{2} \left[\tau y^{\mathrm{T}} y \right] \; .
\end{aligned}
\tag{7}
$$

Next, we have a look at the alternative m_1 assuming $\mu \neq 0$. First, the training data $y_1^{(i)}$ are analyzed using a non-informative prior distribution ($\to$ Definition I/5.2.3) and applying the posterior distribution for the univariate Gaussian with known variance ($\to$ Proof III/1.2.7):

$$
\begin{aligned}
\mu_0^{(1)} &= 0 \\
\lambda_0^{(1)} &= 0 \\
\mu_n^{(1)} &= \frac{\tau n_1 \bar{y}_1^{(i)} + \lambda_0^{(1)} \mu_0^{(1)}}{\tau n_1 + \lambda_0^{(1)}} = \bar{y}_1^{(i)} \\
\lambda_n^{(1)} &= \tau n_1 + \lambda_0^{(1)} = \tau n_1 \; .
\end{aligned}
\tag{8}
$$

This results in a posterior characterized by $\mu_n^{(1)}$ and $\lambda_n^{(1)}$. Then, the test data $y_2^{(i)}$ are analyzed using this posterior as an informative prior distribution ($\rightarrow$ Definition I/5.2.3), again applying the posterior distribution for the univariate Gaussian with known variance ($\rightarrow$ Proof III/1.2.7):

$$
\begin{aligned}
\mu_0^{(2)} &= \mu_n^{(1)} = \bar{y}_1^{(i)} \\
\lambda_0^{(2)} &= \lambda_n^{(1)} = \tau n_1 \\
\mu_n^{(2)} &= \frac{\tau n_2 \bar{y}_2^{(i)} + \lambda_0^{(2)} \mu_0^{(2)}}{\tau n_2 + \lambda_0^{(2)}} = \bar{y} \\
\lambda_n^{(2)} &= \tau n_2 + \lambda_0^{(2)} = \tau n \ .
\end{aligned}
\tag{9}
$$

In the test data, we now have a prior characterized by $\mu_0^{(2)}/\lambda_0^{(2)}$ and a posterior characterized $\mu_n^{(2)}/\lambda_n^{(2)}$. Applying the log model evidence for the univariate Gaussian with known variance ($\rightarrow$ Proof III/1.2.8), the out-of-sample log model evidence ($\rightarrow$ Definition "ooslme") (oosLME) therefore follows as

$$
\begin{aligned}
\mathrm{oosLME}_i(m_1) &= \frac{n_2}{2} \log\left(\frac{\tau}{2\pi}\right) + \frac{1}{2} \log\left(\frac{\lambda_0^{(2)}}{\lambda_n^{(2)}}\right) - \frac{1}{2}\left[\tau y_2^{(i)\mathrm{T}} y_2^{(i)} + \lambda_0^{(2)} \mu_0^{(2)2} - \lambda_n^{(2)} \mu_n^{(2)2}\right] \\
&= \frac{n_2}{2} \log\left(\frac{\tau}{2\pi}\right) + \frac{1}{2} \log\left(\frac{n_1}{n}\right) - \frac{1}{2}\left[\tau y_2^{(i)\mathrm{T}} y_2^{(i)} + \frac{\tau}{n_1}\left(n_1 \bar{y}_1^{(i)}\right)^2 - \frac{\tau}{n}(n\bar{y})^2\right] \ .
\end{aligned}
\tag{10}
$$

Again, because the cross-validated log model evidence is the sum of out-of-sample log model evidences ($\rightarrow$ Definition IV/3.1.5) over cross-validation folds, the cvLME of m_1 becomes:

$$
\begin{aligned}
\mathrm{cvLME}(m_1) &= \sum_{i=1}^{S} \mathrm{oosLME}_i(m_1) \\
&= \sum_{i=1}^{S} \left(\frac{n_2}{2} \log\left(\frac{\tau}{2\pi}\right) + \frac{1}{2} \log\left(\frac{n_1}{n}\right) - \frac{1}{2}\left[\tau y_2^{(i)\mathrm{T}} y_2^{(i)} + \frac{\tau}{n_1}\left(n_1 \bar{y}_1^{(i)}\right)^2 - \frac{\tau}{n}(n\bar{y})^2\right]\right) \\
&= \frac{S \cdot n_2}{2} \log\left(\frac{\tau}{2\pi}\right) + \frac{S}{2} \log\left(\frac{n_1}{n}\right) - \frac{\tau}{2} \sum_{i=1}^{S} \left[y_2^{(i)\mathrm{T}} y_2^{(i)} + \frac{\left(n_1 \bar{y}_1^{(i)}\right)^2}{n_1} - \frac{(n\bar{y})^2}{n}\right] \\
&= \frac{n}{2} \log\left(\frac{\tau}{2\pi}\right) + \frac{S}{2} \log\left(\frac{S-1}{S}\right) - \frac{\tau}{2} \left[y^{\mathrm{T}} y + \sum_{i=1}^{S} \left(\frac{\left(n_1 \bar{y}_1^{(i)}\right)^2}{n_1} - \frac{(n\bar{y})^2}{n}\right)\right] \ .
\end{aligned}
\tag{11}
$$

Together, (7) and (11) conform to the results given in (3).

1.2.13   Cross-validated log Bayes factor

Theorem: Let

$$y = \{y_1, \ldots, y_n\}, \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

be a univariate Gaussian data set ($\rightarrow$ Definition III/1.2.1) with unknown mean μ and known variance σ^2. Moreover, assume two statistical models ($\rightarrow$ Definition I/5.1.4), one assuming that μ is zero (null model ($\rightarrow$ Definition I/4.3.2)), the other imposing a normal distribution ($\rightarrow$ Proof III/1.2.6) as the prior distribution ($\rightarrow$ Definition I/5.1.3) on the model parameter μ (alternative ($\rightarrow$ Definition I/4.3.3)):

$$\begin{aligned} m_0 : \ & y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu = 0 \\ m_1 : \ & y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu \sim \mathcal{N}(\mu_0, \lambda_0^{-1}) \, . \end{aligned} \tag{2}$$

Then, the cross-validated ($\rightarrow$ Definition IV/3.1.5) log Bayes factor ($\rightarrow$ Definition IV/3.3.1) in favor of m_1 against m_0 is

$$\mathrm{cvLBF}_{10} = \frac{S}{2} \log\left(\frac{S-1}{S}\right) - \frac{\tau}{2} \sum_{i=1}^{S} \left(\frac{\left(n_1 \bar{y}_1^{(i)}\right)^2}{n_1} - \frac{(n\bar{y})^2}{n} \right) \tag{3}$$

where $\bar{y}$ is the sample mean ($\rightarrow$ Definition I/1.5.2), $\tau = 1/\sigma^2$ is the inverse variance or precision ($\rightarrow$ Definition I/1.6.11), $y_1^{(i)}$ are the training data in the i-th cross-validation fold and S is the number of data subsets ($\rightarrow$ Definition IV/3.1.5).

Proof: The relationship between log Bayes factor and log model evidences ($\rightarrow$ Proof IV/3.3.3) also holds for cross-validated log bayes factor ($\rightarrow$ Definition IV/3.3.1) (cvLBF) and cross-validated log model evidences ($\rightarrow$ Definition IV/3.1.5) (cvLME):

$$\mathrm{cvLBF}_{12} = \mathrm{cvLME}(m_1) - \mathrm{cvLME}(m_2) \, . \tag{4}$$

The cross-validated log model evidences ($\rightarrow$ Definition IV/3.1.5) of m_0 and m_1 are given by ($\rightarrow$ Proof III/1.2.12)

$$\begin{aligned} \mathrm{cvLME}(m_0) &= \frac{n}{2} \log\left(\frac{\tau}{2\pi}\right) - \frac{1}{2}\left(\tau y^{\mathrm{T}} y\right) \\ \mathrm{cvLME}(m_1) &= \frac{n}{2} \log\left(\frac{\tau}{2\pi}\right) + \frac{S}{2} \log\left(\frac{S-1}{S}\right) - \frac{\tau}{2}\left[y^{\mathrm{T}} y + \sum_{i=1}^{S} \left(\frac{\left(n_1 \bar{y}_1^{(i)}\right)^2}{n_1} - \frac{(n\bar{y})^2}{n} \right) \right] \, . \end{aligned} \tag{5}$$

Subtracting the two cvLMEs from each other, the cvLBF emerges as

$$\text{cvLBF}_{10} = \text{cvLME}(m_1) - \text{LME}(m_0)$$

$$= \left(\frac{n}{2} \log \left(\frac{\tau}{2\pi} \right) + \frac{S}{2} \log \left(\frac{S-1}{S} \right) - \frac{\tau}{2} \left[y^{\mathrm{T}} y + \sum_{i=1}^{S} \left(\frac{\left(n_1 \bar{y}_1^{(i)} \right)^2}{n_1} - \frac{(n\bar{y})^2}{n} \right) \right] \right)$$

$$- \left(\frac{n}{2} \log \left(\frac{\tau}{2\pi} \right) - \frac{1}{2} \left(\tau y^{\mathrm{T}} y \right) \right) \tag{6}$$

$$= \frac{S}{2} \log \left(\frac{S-1}{S} \right) - \frac{\tau}{2} \sum_{i=1}^{S} \left(\frac{\left(n_1 \bar{y}_1^{(i)} \right)^2}{n_1} - \frac{(n\bar{y})^2}{n} \right) .$$

1.2.14 Expectation of cross-validated log Bayes factor

Theorem: Let

$$y = \{ y_1, \ldots, y_n \}, \quad y_i \sim \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \tag{1}$$

be a univariate Gaussian data set ($\to$ Definition III/1.2.1) with unknown mean μ and known variance σ^2. Moreover, assume two statistical models ($\to$ Definition I/5.1.4), one assuming that μ is zero (null model ($\to$ Definition I/4.3.2)), the other imposing a normal distribution ($\to$ Proof III/1.2.6) as the prior distribution ($\to$ Definition I/5.1.3) on the model parameter μ (alternative ($\to$ Definition I/4.3.3)):

$$\begin{aligned} m_0 : \ & y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu = 0 \\ m_1 : \ & y_i \sim \mathcal{N}(\mu, \sigma^2), \ \mu \sim \mathcal{N}(\mu_0, \lambda_0^{-1}) . \end{aligned} \tag{2}$$

Then, the expectation ($\to$ Definition I/1.5.1) of the cross-validated ($\to$ Definition IV/3.1.5) log Bayes factor ($\to$ Definition IV/3.3.1) (cvLBF) in favor of m_1 against m_0 is

$$\langle \text{cvLBF}_{10} \rangle = \frac{S}{2} \log \left(\frac{S-1}{S} \right) + \frac{1}{2} \left[\tau n \mu^2 \right] \tag{3}$$

where $\tau = 1/\sigma^2$ is the inverse variance or precision ($\to$ Definition I/1.6.11) and S is the number of data subsets ($\to$ Definition IV/3.1.5).

Proof: The cross-validated log Bayes factor for the univariate Gaussian with known variance ($\to$ Proof III/1.2.13) is

$$\text{cvLBF}_{10} = \frac{S}{2} \log \left(\frac{S-1}{S} \right) - \frac{\tau}{2} \sum_{i=1}^{S} \left(\frac{\left(n_1 \bar{y}_1^{(i)} \right)^2}{n_1} - \frac{(n\bar{y})^2}{n} \right) \tag{4}$$

From (1), we know that the data are distributed as $y_i \sim \mathcal{N}(\mu, \sigma^2)$, such that we can derive the expectation ($\to$ Definition I/1.5.1) of $(n\bar{y})^2$ and $\left(n_1 \bar{y}_1^{(i)}\right)^2$ as follows:

$$\left\langle (n\bar{y})^2 \right\rangle = \left\langle \sum_{i=1}^{n} \sum_{j=1}^{n} y_i y_j \right\rangle = \left\langle n y_i^2 + (n^2 - n)[y_i y_j]_{i \neq j} \right\rangle$$
$$= n(\mu^2 + \sigma^2) + (n^2 - n)\mu^2$$
$$= n^2 \mu^2 + n\sigma^2 \; . \tag{5}$$

Applying this expected value ($\to$ Definition I/1.5.1) to (4), the expected cvLBF emerges as:

$$\left\langle \mathrm{cvLBF}_{10} \right\rangle = \left\langle \frac{S}{2} \log\left(\frac{S-1}{S}\right) - \frac{\tau}{2} \sum_{i=1}^{S} \left(\frac{\left(n_1 \bar{y}_1^{(i)}\right)^2}{n_1} - \frac{(n\bar{y})^2}{n} \right) \right\rangle$$
$$= \frac{S}{2} \log\left(\frac{S-1}{S}\right) - \frac{\tau}{2} \sum_{i=1}^{S} \left(\frac{\left\langle \left(n_1 \bar{y}_1^{(i)}\right)^2 \right\rangle}{n_1} - \frac{\left\langle (n\bar{y})^2 \right\rangle}{n} \right)$$
$$\overset{(5)}{=} \frac{S}{2} \log\left(\frac{S-1}{S}\right) - \frac{\tau}{2} \sum_{i=1}^{S} \left(\frac{n_1^2 \mu^2 + n_1 \sigma^2}{n_1} - \frac{n^2 \mu^2 + n\sigma^2}{n} \right) \tag{6}$$
$$= \frac{S}{2} \log\left(\frac{S-1}{S}\right) - \frac{\tau}{2} \sum_{i=1}^{S} \left([n_1 \mu^2 + \sigma^2] - [n\mu^2 + \sigma^2] \right)$$
$$= \frac{S}{2} \log\left(\frac{S-1}{S}\right) - \frac{\tau}{2} \sum_{i=1}^{S} (n_1 - n)\mu^2$$

Because it holds that ($\to$ Proof III/1.2.12) $n_1 + n_2 = n$ and $n_2 = n/S$, we finally have:

$$\left\langle \mathrm{cvLBF}_{10} \right\rangle = \frac{S}{2} \log\left(\frac{S-1}{S}\right) - \frac{\tau}{2} \sum_{i=1}^{S} (-n_2)\mu^2$$
$$= \frac{S}{2} \log\left(\frac{S-1}{S}\right) + \frac{1}{2} \left[\tau n \mu^2 \right] \; . \tag{7}$$

1.3   Multiple linear regression

1.3.1   Definition

Definition: Let y be an $n \times 1$ vector and let X be an $n \times p$ matrix.

Then, a statement asserting a linear combination of X into y

$$y = X\beta + \varepsilon , \tag{1}$$

together with a statement asserting a normal distribution ($\rightarrow$ Definition II/4.1.1) for ε

$$\varepsilon \sim \mathcal{N}(0, \sigma^2 V) \tag{2}$$

is called a univariate linear regression model or simply, "multiple linear regression".
- y is called "measured data", "dependent variable" or "measurements";
- X is called "design matrix", "set of independent variables" or "predictors";
- V is called "covariance matrix" or "covariance structure";
- β are called "regression coefficients" or "weights";
- ε is called "noise", "errors" or "error terms";
- σ^2 is called "noise variance" or "error variance";
- n is the number of observations;
- p is the number of predictors.

Alternatively, the linear combination may also be written as

$$y = \sum_{i=1}^{p} \beta_i x_i + \varepsilon \tag{3}$$

or, when the model includes an intercept term, as

$$y = \beta_0 + \sum_{i=1}^{p} \beta_i x_i + \varepsilon \tag{4}$$

which is equivalent to adding a constant regressor $x_0 = 1_n$ to the design matrix X.

When the covariance structure V is equal to the $n \times n$ identity matrix, this is called multiple linear regression with independent and identically distributed (i.i.d.) observations:

$$V = I_n \quad \Rightarrow \quad \varepsilon \sim \mathcal{N}(0, \sigma^2 I_n) \quad \Rightarrow \quad \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) . \tag{5}$$

Otherwise, it is called multiple linear regression with correlated observations.

1.3.2 Ordinary least squares

Theorem: Given a linear regression model ($\rightarrow$ Definition III/1.3.1) with independent observations

$$y = X\beta + \varepsilon, \; \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) , \tag{1}$$

the parameters minimizing the residual sum of squares ($\rightarrow$ Definition III/1.3.6) are given by

$$\hat{\beta} = (X^{\mathrm{T}} X)^{-1} X^{\mathrm{T}} y . \tag{2}$$

Proof: Let $\hat{\beta}$ be the ordinary least squares (OLS) solution and let $\hat{\varepsilon} = y - X\hat{\beta}$ be the resulting vector of residuals. Then, this vector must be orthogonal to the design matrix,

$$X^T \hat{\varepsilon} = 0 \; , \tag{3}$$

because if it wasn't, there would be another solution $\tilde{\beta}$ giving another vector $\tilde{\varepsilon}$ with a smaller residual sum of squares. From (3), the OLS formula can be directly derived:

$$\begin{aligned}
X^T \hat{\varepsilon} &= 0 \\
X^T \left(y - X\hat{\beta} \right) &= 0 \\
X^T y - X^T X \hat{\beta} &= 0 \\
X^T X \hat{\beta} &= X^T y \\
\hat{\beta} &= (X^T X)^{-1} X^T y \; .
\end{aligned} \tag{4}$$

1.3.3   Ordinary least squares

Theorem: Given a linear regression model ($\rightarrow$ Definition III/1.3.1) with independent observations

$$y = X\beta + \varepsilon, \; \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \; , \tag{1}$$

the parameters minimizing the residual sum of squares ($\rightarrow$ Definition III/1.3.6) are given by

$$\hat{\beta} = (X^T X)^{-1} X^T y \; . \tag{2}$$

Proof: The residual sum of squares ($\rightarrow$ Definition III/1.3.6) is defined as

$$\text{RSS}(\beta) = \sum_{i=1}^{n} \varepsilon_i = \varepsilon^T \varepsilon = (y - X\beta)^T (y - X\beta) \tag{3}$$

which can be developed into

$$\begin{aligned}
\text{RSS}(\beta) &= y^T y - y^T X\beta - \beta^T X^T y + \beta^T X^T X\beta \\
&= y^T y - 2\beta^T X^T y + \beta^T X^T X\beta \; .
\end{aligned} \tag{4}$$

The derivative of $\text{RSS}(\beta)$ with respect to β is

$$\frac{\text{dRSS}(\beta)}{\text{d}\beta} = -2X^T y + 2X^T X\beta \tag{5}$$

and setting this deriative to zero, we obtain:

$$\frac{\mathrm{dRSS}(\hat{\beta})}{\mathrm{d}\beta} = 0$$

$$0 = -2X^{\mathrm{T}}y + 2X^{\mathrm{T}}X\hat{\beta} \tag{6}$$

$$X^{\mathrm{T}}X\hat{\beta} = X^{\mathrm{T}}y$$

$$\hat{\beta} = (X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}}y \,.$$

Since the quadratic form $y^{\mathrm{T}}y$ in (4) is positive, $\hat{\beta}$ minimizes $\mathrm{RSS}(\beta)$.

1.3.4 Total sum of squares

Definition: Let there be a multiple linear regression with independent observations ($\rightarrow$ Definition III/1.3.1) using measured data y and design matrix X:

$$y = X\beta + \varepsilon, \ \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \,. \tag{1}$$

Then, the total sum of squares (TSS) is defined as the sum of squared deviations of the measured signal from the average signal:

$$\mathrm{TSS} = \sum_{i=1}^{n}(y_i - \bar{y})^2 \quad \text{where} \quad \bar{y} = \frac{1}{n}\sum_{i=1}^{n}y_i \,. \tag{2}$$

Sources:
- Wikipedia (2020): "Total sum of squares"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-21; URL: https://en.wikipedia.org/wiki/Total_sum_of_squares.

Metadata: ID: D37 | shortcut: tss | author: JoramSoch | date: 2020-03-21, 21:44.

1.3.5 Explained sum of squares

Definition: Let there be a multiple linear regression with independent observations ($\rightarrow$ Definition III/1.3.1) using measured data y and design matrix X:

$$y = X\beta + \varepsilon, \ \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \,. \tag{1}$$

Then, the explained sum of squares (ESS) is defined as the sum of squared deviations of the fitted signal from the average signal:

$$\mathrm{ESS} = \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2 \quad \text{where} \quad \hat{y} = X\hat{\beta} \quad \text{and} \quad \bar{y} = \frac{1}{n}\sum_{i=1}^{n}y_i \tag{2}$$

with estimated regression coefficients $\hat{\beta}$, e.g. obtained via ordinary least squares ($\rightarrow$ Proof III/1.3.2).

Sources:
* Wikipedia (2020): "Explained sum of squares"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-21; URL: https://en.wikipedia.org/wiki/Explained_sum_of_squares.

Metadata: ID: D38 | shortcut: ess | author: JoramSoch | date: 2020-03-21, 21:57.

1.3.6   Residual sum of squares

Definition: Let there be a multiple linear regression with independent observations ($\rightarrow$ Definition III/1.3.1) using measured data y and design matrix X:

$$y = X\beta + \varepsilon, \ \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \ . \tag{1}$$

Then, the residual sum of squares (RSS) is defined as the sum of squared deviations of the measured signal from the fitted signal:

$$\text{RSS} = \sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \quad \text{where} \quad \hat{y} = X\hat{\beta} \tag{2}$$

with estimated regression coefficients $\hat{\beta}$, e.g. obtained via ordinary least squares ($\rightarrow$ Proof III/1.3.2).

Sources:
* Wikipedia (2020): "Residual sum of squares"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-21; URL: https://en.wikipedia.org/wiki/Residual_sum_of_squares.

Metadata: ID: D39 | shortcut: rss | author: JoramSoch | date: 2020-03-21, 22:03.

1.3.7   Total, explained and residual sum of squares

Theorem: Assume a linear regression model ($\rightarrow$ Definition III/1.3.1) with independent observations

$$y = X\beta + \varepsilon, \ \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \ , \tag{1}$$

and let X contain a constant regressor 1_n modelling the intercept term. Then, it holds that

$$\text{TSS} = \text{ESS} + \text{RSS} \tag{2}$$

where TSS is the total sum of squares ($\rightarrow$ Definition III/1.3.4), ESS is the explained sum of squares ($\rightarrow$ Definition III/1.3.5) and RSS is the residual sum of squares ($\rightarrow$ Definition III/1.3.6).

Proof: The total sum of squares ($\rightarrow$ Definition III/1.3.4) is given by

$$\text{TSS} = \sum_{i=1}^{n}(y_i - \bar{y})^2 \tag{3}$$

where $\bar{y}$ is the mean across all y_i. The TSS can be rewritten as

$$
\begin{aligned}
\text{TSS} &= \sum_{i=1}^{n}(y_i - \bar{y} + \hat{y}_i - \hat{y}_i)^2 \\
&= \sum_{i=1}^{n}\left((\hat{y}_i - \bar{y}) + (y_i - \hat{y}_i)\right)^2 \\
&= \sum_{i=1}^{n}\left((\hat{y}_i - \bar{y}) + \hat{\varepsilon}_i\right)^2 \\
&= \sum_{i=1}^{n}\left((\hat{y}_i - \bar{y})^2 + 2\,\hat{\varepsilon}_i(\hat{y}_i - \bar{y}) + \hat{\varepsilon}_i^2\right) \\
&= \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2 + \sum_{i=1}^{n}\hat{\varepsilon}_i^2 + 2\sum_{i=1}^{n}\hat{\varepsilon}_i(\hat{y}_i - \bar{y}) \\
&= \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2 + \sum_{i=1}^{n}\hat{\varepsilon}_i^2 + 2\sum_{i=1}^{n}\hat{\varepsilon}_i(x_i\hat{\beta} - \bar{y}) \\
&= \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2 + \sum_{i=1}^{n}\hat{\varepsilon}_i^2 + 2\sum_{i=1}^{n}\hat{\varepsilon}_i\left(\sum_{j=1}^{p}x_{ij}\hat{\beta}_j\right) - 2\sum_{i=1}^{n}\hat{\varepsilon}_i\,\bar{y} \\
&= \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2 + \sum_{i=1}^{n}\hat{\varepsilon}_i^2 + 2\sum_{j=1}^{p}\hat{\beta}_j\sum_{i=1}^{n}\hat{\varepsilon}_i x_{ij} - 2\bar{y}\sum_{i=1}^{n}\hat{\varepsilon}_i
\end{aligned}
\tag{4}
$$

The fact that the design matrix includes a constant regressor ensures that

$$
\sum_{i=1}^{n}\hat{\varepsilon}_i = \hat{\varepsilon}^{\mathrm{T}}1_n = 0
\tag{5}
$$

and because the residuals are orthogonal to the design matrix ($\rightarrow$ Proof III/1.3.2), we have

$$
\sum_{i=1}^{n}\hat{\varepsilon}_i x_{ij} = \hat{\varepsilon}^{\mathrm{T}}x_j = 0 \;.
\tag{6}
$$

Applying (5) and (6) to (4), this becomes

$$
\text{TSS} = \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2 + \sum_{i=1}^{n}\hat{\varepsilon}_i^2
\tag{7}
$$

and, with the definitions of explained ($\rightarrow$ Definition III/1.3.5) and residual sum of squares ($\rightarrow$ Definition III/1.3.6), it is

$$
\text{TSS} = \text{ESS} + \text{RSS} \;.
\tag{8}
$$

1.3.8　Estimation matrix

Definition: In multiple linear regression ($\rightarrow$ Definition III/1.3.1), the estimation matrix is the matrix E that results in ordinary least squares ($\rightarrow$ Proof III/1.3.2) or weighted least squares ($\rightarrow$ Proof III/1.3.13) parameter estimates when right-multiplied with the measured data:

$$Ey = \hat{\beta} \; . \tag{1}$$

Sources:
- original work

Metadata: ID: D81 | shortcut: emat | author: JoramSoch | date: 2020-07-22, 05:17.

1.3.9　Projection matrix

Definition: In multiple linear regression ($\rightarrow$ Definition III/1.3.1), the projection matrix is the matrix P that results in the fitted signal explained by estimated parameters ($\rightarrow$ Definition III/1.3.8) when right-multiplied with the measured data:

$$Py = \hat{y} = X\hat{\beta} \; . \tag{1}$$

Sources:
- Wikipedia (2020): "Projection matrix"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-07-22; URL: https://en.wikipedia.org/wiki/Projection_matrix#Overview.

Metadata: ID: D82 | shortcut: pmat | author: JoramSoch | date: 2020-07-22, 05:25.

1.3.10　Residual-forming matrix

Definition: In multiple linear regression ($\rightarrow$ Definition III/1.3.1), the residual-forming matrix is the matrix R that results in the vector of residuals left over by estimated parameters ($\rightarrow$ Definition III/1.3.8) when right-multiplied with the measured data:

$$Ry = \hat{\varepsilon} = y - \hat{y} = y - X\hat{\beta} \; . \tag{1}$$

Sources:
- Wikipedia (2020): "Projection matrix"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-07-22; URL: https://en.wikipedia.org/wiki/Projection_matrix#Properties.

Metadata: ID: D83 | shortcut: rfmat | author: JoramSoch | date: 2020-07-22, 05:35.

1.3.11　Estimation, projection and residual-forming matrix

Theorem: Assume a linear regression model ($\rightarrow$ Definition III/1.3.1) with independent observations

$$y = X\beta + \varepsilon, \; \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \tag{1}$$

and consider estimation using ordinary least squares ($\rightarrow$ Proof III/1.3.2). Then, the estimated parameters, fitted signal and residuals are given by

$$
\begin{aligned}
\hat{\beta} &= Ey \\
\hat{y} &= Py \\
\hat{\varepsilon} &= Ry
\end{aligned}
\tag{2}
$$

where

$$
\begin{aligned}
E &= (X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}} \\
P &= X(X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}} \\
R &= I_n - X(X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}}
\end{aligned}
\tag{3}
$$

are the estimation matrix ($\rightarrow$ Definition III/1.3.8), projection matrix ($\rightarrow$ Definition III/1.3.9) and residual-forming matrix ($\rightarrow$ Definition III/1.3.10) and n is the number of observations.

Proof:
1) Ordinary least squares parameter estimates of β are defined as minimizing the residual sum of squares ($\rightarrow$ Definition III/1.3.6)

$$
\hat{\beta} = \arg \min_{\beta} \left[(y - X\beta)^{\mathrm{T}}(y - X\beta) \right]
\tag{4}
$$

and the solution to this ($\rightarrow$ Proof III/1.3.2) is given by

$$
\begin{aligned}
\hat{\beta} &= (X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}}y \\
&\overset{(3)}{=} Ey \, .
\end{aligned}
\tag{5}
$$

2) The fitted signal is given by multiplying the design matrix with the estimated regression coefficients

$$
\hat{y} = X\hat{\beta}
\tag{6}
$$

and using (5), this becomes

$$
\begin{aligned}
\hat{y} &= X(X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}}y \\
&\overset{(3)}{=} Py \, .
\end{aligned}
\tag{7}
$$

3) The residuals of the model are calculated by subtracting the fitted signal from the measured signal

$$
\hat{\varepsilon} = y - \hat{y}
\tag{8}
$$

and using (7), this becomes

$$
\begin{aligned}
\hat{\varepsilon} &= y - X(X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}}y \\
&= (I_n - X(X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}})y \\
&\overset{(3)}{=} Ry \, .
\end{aligned}
\tag{9}
$$

1.3.12   Idempotence of projection and residual-forming matrix

Theorem: The projection matrix ($\to$ Definition III/1.3.9) and the residual-forming matrix ($\to$ Definition III/1.3.10) are idempotent:

$$
\begin{aligned}
P^2 &= P \\
R^2 &= R \; .
\end{aligned}
\tag{1}
$$

Proof:
1) The projection matrix for ordinary least squares is given by ($\to$ Proof III/1.3.11)

$$
P = X(X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}} \; ,
\tag{2}
$$

such that

$$
\begin{aligned}
P^2 &= X(X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}}X(X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}} \\
&= X(X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}} \\
&\overset{(2)}{=} P \; .
\end{aligned}
\tag{3}
$$

2) The residual-forming matrix for ordinary least squares is given by ($\to$ Proof III/1.3.11)

$$
R = I_n - X(X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}} = I_n - P \; ,
\tag{4}
$$

such that

$$
\begin{aligned}
R^2 &= (I_n - P)(I_n - P) \\
&= I_n - P - P + P^2 \\
&\overset{(3)}{=} I_n - 2P + P \\
&= I_n - P \\
&\overset{(4)}{=} R \; .
\end{aligned}
\tag{5}
$$

1.3.13 Weighted least squares

Theorem: Given a linear regression model ($\rightarrow$ Definition III/1.3.1) with correlated observations

$$y = X\beta + \varepsilon, \ \varepsilon \sim \mathcal{N}(0, \sigma^2 V) , \tag{1}$$

the parameters minimizing the weighted residual sum of squares ($\rightarrow$ Definition III/1.3.6) are given by

$$\hat{\beta} = (X^\mathrm{T} V^{-1} X)^{-1} X^\mathrm{T} V^{-1} y . \tag{2}$$

Proof: Let there be an $n \times n$ square matrix W, such that

$$WVW^\mathrm{T} = I_n . \tag{3}$$

Since V is a covariance matrix and thus symmetric, W is also symmetric and can be expressed as the matrix square root of the inverse of V:

$$WVW = I_n \quad \Leftrightarrow \quad V = W^{-1}W^{-1} \quad \Leftrightarrow \quad V^{-1} = WW \quad \Leftrightarrow \quad W = V^{-1/2} . \tag{4}$$

Left-multiplying the linear regression equation (1) with W, the linear transformation theorem ($\rightarrow$ Proof II/4.1.5) implies that

$$Wy = WX\beta + W\varepsilon, \ W\varepsilon \sim \mathcal{N}(0, \sigma^2 WVW^T) . \tag{5}$$

Applying (3), we see that (5) is actually a linear regression model ($\rightarrow$ Definition III/1.3.1) with independent observations

$$\tilde{y} = \tilde{X}\beta + \tilde{\varepsilon}, \ \tilde{\varepsilon} \sim \mathcal{N}(0, \sigma^2 I_n) \tag{6}$$

where $\tilde{y} = Wy$, $\tilde{X} = WX$ and $\tilde{\varepsilon} = W\varepsilon$, such that we can apply the ordinary least squares solution ($\rightarrow$ Proof III/1.3.2) giving

$$\begin{aligned}
\hat{\beta} &= (\tilde{X}^\mathrm{T}\tilde{X})^{-1}\tilde{X}^\mathrm{T}\tilde{y} \\
&= \left((WX)^\mathrm{T}WX\right)^{-1}(WX)^\mathrm{T}Wy \\
&= \left(X^\mathrm{T}W^\mathrm{T}WX\right)^{-1}X^\mathrm{T}W^\mathrm{T}Wy \\
&= \left(X^\mathrm{T}WWX\right)^{-1}X^\mathrm{T}WWy \\
&\overset{(4)}{=} \left(X^\mathrm{T}V^{-1}X\right)^{-1}X^\mathrm{T}V^{-1}y
\end{aligned} \tag{7}$$

which corresponds to the weighted least squares solution (2).

1.3.14 Weighted least squares

Theorem: Given a linear regression model ($\rightarrow$ Definition III/1.3.1) with correlated observations

$$y = X\beta + \varepsilon, \ \varepsilon \sim \mathcal{N}(0, \sigma^2 V) \ , \tag{1}$$

the parameters minimizing the weighted residual sum of squares ($\rightarrow$ Definition III/1.3.6) are given by

$$\hat{\beta} = (X^\mathrm{T} V^{-1} X)^{-1} X^\mathrm{T} V^{-1} y \ . \tag{2}$$

Proof: Let there be an $n \times n$ square matrix W, such that

$$WVW^\mathrm{T} = I_n \ . \tag{3}$$

Since V is a covariance matrix and thus symmetric, W is also symmetric and can be expressed the matrix square root of the inverse of V:

$$WVW = I_n \quad \Leftrightarrow \quad V = W^{-1}W^{-1} \quad \Leftrightarrow \quad V^{-1} = WW \quad \Leftrightarrow \quad W = V^{-1/2} \ . \tag{4}$$

Left-multiplying the linear regression equation (1) with W, the linear transformation theorem ($\rightarrow$ Proof II/4.1.5) implies that

$$Wy = WX\beta + W\varepsilon, \ W\varepsilon \sim \mathcal{N}(0, \sigma^2 WVW^T) \ . \tag{5}$$

Applying (3), we see that (5) is actually a linear regression model ($\rightarrow$ Definition III/1.3.1) with independent observations

$$Wy = WX\beta + W\varepsilon, \ W\varepsilon \sim \mathcal{N}(0, \sigma^2 I_n) \ . \tag{6}$$

With this, we can express the weighted residual sum of squares ($\rightarrow$ Definition III/1.3.6) as

$$\mathrm{wRSS}(\beta) = \sum_{i=1}^{n}(W\varepsilon)_i = (W\varepsilon)^\mathrm{T}(W\varepsilon) = (Wy - WX\beta)^\mathrm{T}(Wy - WX\beta) \tag{7}$$

which can be developed into

$$\begin{aligned}
\mathrm{wRSS}(\beta) &= y^\mathrm{T}W^\mathrm{T}Wy - y^\mathrm{T}W^\mathrm{T}WX\beta - \beta^\mathrm{T}X^\mathrm{T}W^\mathrm{T}Wy + \beta^\mathrm{T}X^\mathrm{T}W^\mathrm{T}WX\beta \\
&= y^\mathrm{T}WWy - 2\beta^\mathrm{T}X^\mathrm{T}WWy + \beta^\mathrm{T}X^\mathrm{T}WWX\beta \\
&\overset{(4)}{=} y^\mathrm{T}V^{-1}y - 2\beta^\mathrm{T}X^\mathrm{T}V^{-1}y + \beta^\mathrm{T}X^\mathrm{T}V^{-1}X\beta \ .
\end{aligned} \tag{8}$$

The derivative of $\mathrm{wRSS}(\beta)$ with respect to β is

$$\frac{\mathrm{dwRSS}(\beta)}{\mathrm{d}\beta} = -2X^\mathrm{T}V^{-1}y + 2X^\mathrm{T}V^{-1}X\beta \tag{9}$$

and setting this deriative to zero, we obtain:

$$\frac{\text{dwRSS}(\hat{\beta})}{\text{d}\beta} = 0$$

$$0 = -2X^{\mathrm{T}}V^{-1}y + 2X^{\mathrm{T}}V^{-1}X\hat{\beta} \tag{10}$$

$$X^{\mathrm{T}}V^{-1}X\hat{\beta} = X^{\mathrm{T}}V^{-1}y$$

$$\hat{\beta} = (X^{\mathrm{T}}V^{-1}X)^{-1}X^{\mathrm{T}}V^{-1}y \; .$$

Since the quadratic form $y^{\mathrm{T}}V^{-1}y$ in (8) is positive, $\hat{\beta}$ minimizes wRSS(β).

1.3.15 Maximum likelihood estimation

Theorem: Given a linear regression model ($\rightarrow$ Definition III/1.3.1) with correlated observations

$$y = X\beta + \varepsilon, \; \varepsilon \sim \mathcal{N}(0, \sigma^2 V) \; , \tag{1}$$

the maximum likelihood estimates ($\rightarrow$ Definition I/4.1.3) of β and σ^2 are given by

$$\hat{\beta} = (X^{\mathrm{T}}V^{-1}X)^{-1}X^{\mathrm{T}}V^{-1}y$$

$$\hat{\sigma}^2 = \frac{1}{n}(y - X\hat{\beta})^{\mathrm{T}}(y - X\hat{\beta}) \; . \tag{2}$$

Proof: With the probability density function of the multivariate normal distribution ($\rightarrow$ Proof II/4.1.2), the linear regression equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$p(y|\beta, \sigma^2) = \mathcal{N}(y; X\beta, \sigma^2 V)$$

$$= \sqrt{\frac{1}{(2\pi)^n |\sigma^2 V|}} \cdot \exp\left[-\frac{1}{2}(y - X\beta)^{\mathrm{T}}(\sigma^2 V)^{-1}(y - X\beta)\right] \tag{3}$$

and, using $|\sigma^2 V| = (\sigma^2)^n |V|$, the log-likelihood function ($\rightarrow$ Definition I/4.1.2)

$$\text{LL}(\beta, \sigma^2) = \log p(y|\beta, \sigma^2)$$

$$= -\frac{n}{2}\log(2\pi) - \frac{n}{2}\log(\sigma^2) - \frac{1}{2}\log|V| \tag{4}$$

$$- \frac{1}{2\sigma^2}(y - X\beta)^{\mathrm{T}}V^{-1}(y - X\beta) \; .$$

Substituting the precision matrix $P = V^{-1}$ into (4) to ease notation, we have:

$$\text{LL}(\beta, \sigma^2) = -\frac{n}{2}\log(2\pi) - \frac{n}{2}\log(\sigma^2) - \frac{1}{2}\log(|V|)$$
$$- \frac{1}{2\sigma^2}\left(y^{\text{T}}Py - 2\beta^{\text{T}}X^{\text{T}}Py + \beta^{\text{T}}X^{\text{T}}PX\beta\right) .$$

(5)

The derivative of the log-likelihood function (5) with respect to β is

$$\frac{\text{dLL}(\beta, \sigma^2)}{\text{d}\beta} = \frac{\text{d}}{\text{d}\beta}\left(-\frac{1}{2\sigma^2}\left(y^{\text{T}}Py - 2\beta^{\text{T}}X^{\text{T}}Py + \beta^{\text{T}}X^{\text{T}}PX\beta\right)\right)$$
$$= \frac{1}{2\sigma^2}\frac{\text{d}}{\text{d}\beta}\left(2\beta^{\text{T}}X^{\text{T}}Py - \beta^{\text{T}}X^{\text{T}}PX\beta\right)$$
$$= \frac{1}{2\sigma^2}\left(2X^{\text{T}}Py - 2X^{\text{T}}PX\beta\right)$$
$$= \frac{1}{\sigma^2}\left(X^{\text{T}}Py - X^{\text{T}}PX\beta\right)$$

(6)

and setting this derivative to zero gives the MLE for β:

$$\frac{\text{dLL}(\hat{\beta}, \sigma^2)}{\text{d}\beta} = 0$$
$$0 = \frac{1}{\sigma^2}\left(X^{\text{T}}Py - X^{\text{T}}PX\hat{\beta}\right)$$
$$0 = X^{\text{T}}Py - X^{\text{T}}PX\hat{\beta}$$
$$X^{\text{T}}PX\hat{\beta} = X^{\text{T}}Py$$
$$\hat{\beta} = \left(X^{\text{T}}PX\right)^{-1}X^{\text{T}}Py$$

(7)

The derivative of the log-likelihood function (4) at $\hat{\beta}$ with respect to σ^2 is

$$\frac{\text{dLL}(\hat{\beta}, \sigma^2)}{\text{d}\sigma^2} = \frac{\text{d}}{\text{d}\sigma^2}\left(-\frac{n}{2}\log(\sigma^2) - \frac{1}{2\sigma^2}(y - X\hat{\beta})^{\text{T}}V^{-1}(y - X\hat{\beta})\right)$$
$$= -\frac{n}{2}\frac{1}{\sigma^2} + \frac{1}{2(\sigma^2)^2}(y - X\hat{\beta})^{\text{T}}V^{-1}(y - X\hat{\beta})$$
$$= -\frac{n}{2\sigma^2} + \frac{1}{2(\sigma^2)^2}(y - X\hat{\beta})^{\text{T}}V^{-1}(y - X\hat{\beta})$$

(8)

and setting this derivative to zero gives the MLE for σ^2:

$$\frac{\mathrm{dLL}(\hat{\beta}, \hat{\sigma}^2)}{\mathrm{d}\sigma^2} = 0$$

$$0 = -\frac{n}{2\hat{\sigma}^2} + \frac{1}{2(\hat{\sigma}^2)^2}(y - X\hat{\beta})^{\mathrm{T}}V^{-1}(y - X\hat{\beta})$$

$$\frac{n}{2\hat{\sigma}^2} = \frac{1}{2(\hat{\sigma}^2)^2}(y - X\hat{\beta})^{\mathrm{T}}V^{-1}(y - X\hat{\beta}) \tag{9}$$

$$\frac{2(\hat{\sigma}^2)^2}{n} \cdot \frac{n}{2\hat{\sigma}^2} = \frac{2(\hat{\sigma}^2)^2}{n} \cdot \frac{1}{2(\hat{\sigma}^2)^2}(y - X\hat{\beta})^{\mathrm{T}}V^{-1}(y - X\hat{\beta})$$

$$\hat{\sigma}^2 = \frac{1}{n}(y - X\hat{\beta})^{\mathrm{T}}V^{-1}(y - X\hat{\beta})$$

Together, (7) and (9) constitute the MLE for multiple linear regression.

1.4 Bayesian linear regression

1.4.1 Conjugate prior distribution

Theorem: Let

$$y = X\beta + \varepsilon, \ \varepsilon \sim \mathcal{N}(0, \sigma^2 V) \tag{1}$$

be a linear regression model ($\rightarrow$ Definition III/1.3.1) with measured $n \times 1$ data vector y, known $n \times p$ design matrix X, known $n \times n$ covariance structure V as well as unknown $p \times 1$ regression coefficients β and unknown noise variance σ^2.

Then, the conjugate prior ($\rightarrow$ Definition I/5.2.5) for this model is a normal-gamma distribution ($\rightarrow$ Definition II/4.3.1)

$$p(\beta, \tau) = \mathcal{N}(\beta; \mu_0, (\tau \Lambda_0)^{-1}) \cdot \mathrm{Gam}(\tau; a_0, b_0) \tag{2}$$

where $\tau = 1/\sigma^2$ is the inverse noise variance or noise precision.

Proof: By definition, a conjugate prior ($\rightarrow$ Definition I/5.2.5) is a prior distribution ($\rightarrow$ Definition I/5.1.3) that, when combined with the likelihood function ($\rightarrow$ Definition I/5.1.2), leads to a posterior distribution ($\rightarrow$ Definition I/5.1.7) that belongs to the same family of probability distributions ($\rightarrow$ Definition I/1.3.1). This is fulfilled when the prior density and the likelihood function are proportional to the model parameters in the same way, i.e. the model parameters appear in the same functional form in both.

Equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$p(y|\beta, \sigma^2) = \mathcal{N}(y; X\beta, \sigma^2 V) = \sqrt{\frac{1}{(2\pi)^n |\sigma^2 V|}} \exp\left[-\frac{1}{2\sigma^2}(y - X\beta)^{\mathrm{T}}V^{-1}(y - X\beta)\right] \tag{3}$$

which, for mathematical convenience, can also be parametrized as

$$p(y|\beta,\tau) = \mathcal{N}(y; X\beta, (\tau P)^{-1}) = \sqrt{\frac{|\tau P|}{(2\pi)^n}} \exp\left[-\frac{\tau}{2}(y-X\beta)^{\mathrm{T}}P(y-X\beta)\right] \qquad (4)$$

using the noise precision $\tau = 1/\sigma^2$ and the $n \times n$ precision matrix $P = V^{-1}$.

Seperating constant and variable terms, we have:

$$p(y|\beta,\tau) = \sqrt{\frac{|P|}{(2\pi)^n}} \cdot \tau^{n/2} \cdot \exp\left[-\frac{\tau}{2}(y-X\beta)^{\mathrm{T}}P(y-X\beta)\right] . \qquad (5)$$

Expanding the product in the exponent, we have:

$$p(y|\beta,\tau) = \sqrt{\frac{|P|}{(2\pi)^n}} \cdot \tau^{n/2} \cdot \exp\left[-\frac{\tau}{2}\left(y^{\mathrm{T}}Py - y^{\mathrm{T}}PX\beta - \beta^{\mathrm{T}}X^{\mathrm{T}}Py + \beta^{\mathrm{T}}X^{\mathrm{T}}PX\beta\right)\right] . \qquad (6)$$

Completing the square over β, finally gives

$$p(y|\beta,\tau) = \sqrt{\frac{|P|}{(2\pi)^n}} \cdot \tau^{n/2} \cdot \exp\left[-\frac{\tau}{2}\left((\beta - \tilde{X}y)^{\mathrm{T}}X^{\mathrm{T}}PX(\beta - \tilde{X}y) - y^{\mathrm{T}}Qy + y^{\mathrm{T}}Py\right)\right] \qquad (7)$$

where $\tilde{X} = \left(X^{\mathrm{T}}PX\right)^{-1}X^{\mathrm{T}}P$ and $Q = \tilde{X}^{\mathrm{T}}\left(X^{\mathrm{T}}PX\right)\tilde{X}$.

In other words, the likelihood function ($\to$ Definition I/5.1.2) is proportional to a power of τ, times an exponential of τ and an exponential of a squared form of β, weighted by τ:

$$p(y|\beta,\tau) \propto \tau^{n/2} \cdot \exp\left[-\frac{\tau}{2}\left(y^{\mathrm{T}}Py - y^{\mathrm{T}}Qy\right)\right] \cdot \exp\left[-\frac{\tau}{2}(\beta - \tilde{X}y)^{\mathrm{T}}X^{\mathrm{T}}PX(\beta - \tilde{X}y)\right] . \qquad (8)$$

The same is true for a normal-gamma distribution ($\to$ Definition II/4.3.1) over β and τ

$$p(\beta,\tau) = \mathcal{N}(\beta; \mu_0, (\tau\Lambda_0)^{-1}) \cdot \mathrm{Gam}(\tau; a_0, b_0) \qquad (9)$$

the probability density function of which ($\to$ Proof II/4.3.2)

$$p(\beta,\tau) = \sqrt{\frac{|\tau\Lambda_0|}{(2\pi)^p}} \exp\left[-\frac{\tau}{2}(\beta - \mu_0)^{\mathrm{T}}\Lambda_0(\beta - \mu_0)\right] \cdot \frac{b_0{}^{a_0}}{\Gamma(a_0)} \tau^{a_0-1}\exp[-b_0\tau] \qquad (10)$$

exhibits the same proportionality

$$p(\beta,\tau) \propto \tau^{a_0+p/2-1} \cdot \exp[-\tau b_0] \cdot \exp\left[-\frac{\tau}{2}(\beta - \mu_0)^{\mathrm{T}}\Lambda_0(\beta - \mu_0)\right] \qquad (11)$$

and is therefore conjugate relative to the likelihood.

1.4.2 Posterior distribution

Theorem: Let

$$y = X\beta + \varepsilon, \ \varepsilon \sim \mathcal{N}(0, \sigma^2 V) \tag{1}$$

be a linear regression model ($\rightarrow$ Definition III/1.3.1) with measured $n \times 1$ data vector y, known $n \times p$ design matrix X, known $n \times n$ covariance structure V as well as unknown $p \times 1$ regression coefficients β and unknown noise variance σ^2. Moreover, assume a normal-gamma prior distribution ($\rightarrow$ Proof III/1.4.1) over the model parameters β and $\tau = 1/\sigma^2$:

$$p(\beta, \tau) = \mathcal{N}(\beta; \mu_0, (\tau\Lambda_0)^{-1}) \cdot \text{Gam}(\tau; a_0, b_0) \ . \tag{2}$$

Then, the posterior distribution ($\rightarrow$ Definition I/5.1.7) is also a normal-gamma distribution ($\rightarrow$ Definition II/4.3.1)

$$p(\beta, \tau | y) = \mathcal{N}(\beta; \mu_n, (\tau\Lambda_n)^{-1}) \cdot \text{Gam}(\tau; a_n, b_n) \tag{3}$$

and the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$\begin{aligned}
\mu_n &= \Lambda_n^{-1}(X^{\text{T}}Py + \Lambda_0\mu_0) \\
\Lambda_n &= X^{\text{T}}PX + \Lambda_0 \\
a_n &= a_0 + \frac{n}{2} \\
b_n &= b_0 + \frac{1}{2}(y^{\text{T}}Py + \mu_0^{\text{T}}\Lambda_0\mu_0 - \mu_n^{\text{T}}\Lambda_n\mu_n) \ .
\end{aligned} \tag{4}$$

Proof: According to Bayes' theorem ($\rightarrow$ Proof I/5.3.1), the posterior distribution ($\rightarrow$ Definition I/5.1.7) is given by

$$p(\beta, \tau | y) = \frac{p(y | \beta, \tau) \, p(\beta, \tau)}{p(y)} \ . \tag{5}$$

Since $p(y)$ is just a normalization factor, the posterior is proportional ($\rightarrow$ Proof I/5.1.8) to the numerator:

$$p(\beta, \tau | y) \propto p(y | \beta, \tau) \, p(\beta, \tau) = p(y, \beta, \tau) \ . \tag{6}$$

Equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$p(y | \beta, \sigma^2) = \mathcal{N}(y; X\beta, \sigma^2 V) = \sqrt{\frac{1}{(2\pi)^n |\sigma^2 V|}} \, \exp\left[-\frac{1}{2\sigma^2}(y - X\beta)^{\text{T}}V^{-1}(y - X\beta)\right] \tag{7}$$

which, for mathematical convenience, can also be parametrized as

$$p(y | \beta, \tau) = \mathcal{N}(y; X\beta, (\tau P)^{-1}) = \sqrt{\frac{|\tau P|}{(2\pi)^n}} \, \exp\left[-\frac{\tau}{2}(y - X\beta)^{\text{T}}P(y - X\beta)\right] \tag{8}$$

using the noise precision $\tau = 1/\sigma^2$ and the $n \times n$ precision matrix ($\rightarrow$ Definition I/1.7.9) $P = V^{-1}$.

Combining the likelihood function ($\rightarrow$ Definition I/5.1.2) (8) with the prior distribution ($\rightarrow$ Definition I/5.1.3) (2), the joint likelihood ($\rightarrow$ Definition I/5.1.5) of the model is given by

$$p(y, \beta, \tau) = p(y|\beta, \tau)\, p(\beta, \tau)$$

$$= \sqrt{\frac{|\tau P|}{(2\pi)^n}} \, \exp\left[-\frac{\tau}{2}(y - X\beta)^{\mathrm{T}} P(y - X\beta)\right] \cdot$$

$$\sqrt{\frac{|\tau\Lambda_0|}{(2\pi)^p}} \, \exp\left[-\frac{\tau}{2}(\beta - \mu_0)^{\mathrm{T}}\Lambda_0(\beta - \mu_0)\right] \cdot \tag{9}$$

$$\frac{b_0{}^{a_0}}{\Gamma(a_0)} \, \tau^{a_0-1} \exp[-b_0\tau] \,.$$

Collecting identical variables gives:

$$p(y, \beta, \tau) = \sqrt{\frac{\tau^{n+p}}{(2\pi)^{n+p}}|P||\Lambda_0|} \, \frac{b_0{}^{a_0}}{\Gamma(a_0)} \, \tau^{a_0-1} \exp[-b_0\tau] \cdot$$

$$\exp\left[-\frac{\tau}{2}\left((y - X\beta)^{\mathrm{T}} P(y - X\beta) + (\beta - \mu_0)^{\mathrm{T}}\Lambda_0(\beta - \mu_0)\right)\right] \,. \tag{10}$$

Expanding the products in the exponent gives:

$$p(y, \beta, \tau) = \sqrt{\frac{\tau^{n+p}}{(2\pi)^{n+p}}|P||\Lambda_0|} \, \frac{b_0{}^{a_0}}{\Gamma(a_0)} \, \tau^{a_0-1} \exp[-b_0\tau] \cdot$$

$$\exp\left[-\frac{\tau}{2}\left(y^{\mathrm{T}} Py - y^{\mathrm{T}} PX\beta - \beta^{\mathrm{T}} X^{\mathrm{T}} Py + \beta^{\mathrm{T}} X^{\mathrm{T}} PX\beta + \right.\right. \tag{11}$$

$$\left.\left. \beta^{\mathrm{T}}\Lambda_0\beta - \beta^{\mathrm{T}}\Lambda_0\mu_0 - \mu_0^{\mathrm{T}}\Lambda_0\beta + \mu_0^{\mathrm{T}}\Lambda_0\mu_0\right)\right] \,.$$

Completing the square over β, we finally have

$$p(y, \beta, \tau) = \sqrt{\frac{\tau^{n+p}}{(2\pi)^{n+p}}|P||\Lambda_0|} \, \frac{b_0{}^{a_0}}{\Gamma(a_0)} \, \tau^{a_0-1} \exp[-b_0\tau] \cdot$$

$$\exp\left[-\frac{\tau}{2}\left((\beta - \mu_n)^{\mathrm{T}}\Lambda_n(\beta - \mu_n) + (y^{\mathrm{T}} Py + \mu_0^{\mathrm{T}}\Lambda_0\mu_0 - \mu_n^{\mathrm{T}}\Lambda_n\mu_n)\right)\right] \tag{12}$$

with the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7)

$$\mu_n = \Lambda_n^{-1}(X^{\mathrm{T}} Py + \Lambda_0\mu_0)$$
$$\Lambda_n = X^{\mathrm{T}} PX + \Lambda_0 \,. \tag{13}$$

Ergo, the joint likelihood is proportional to

$$p(y, \beta, \tau) \propto \tau^{p/2} \cdot \exp\left[-\frac{\tau}{2}(\beta - \mu_n)^{\mathrm{T}}\Lambda_n(\beta - \mu_n)\right] \cdot \tau^{a_n-1} \cdot \exp\left[-b_n\tau\right] \tag{14}$$

with the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7)

$$a_n = a_0 + \frac{n}{2}$$
$$b_n = b_0 + \frac{1}{2}(y^{\mathrm{T}} Py + \mu_0^{\mathrm{T}}\Lambda_0\mu_0 - \mu_n^{\mathrm{T}}\Lambda_n\mu_n) \,. \tag{15}$$

From the term in (14), we can isolate the posterior distribution over β given τ:

$$p(\beta|\tau, y) = \mathcal{N}(\beta; \mu_n, (\tau\Lambda_n)^{-1}) . \tag{16}$$

From the remaining term, we can isolate the posterior distribution over τ:

$$p(\tau|y) = \text{Gam}(\tau; a_n, b_n) . \tag{17}$$

Together, (16) and (17) constitute the joint ($\rightarrow$ Definition I/1.2.2) posterior distribution ($\rightarrow$ Definition I/5.1.7) of β and τ.

1.4.3 Log model evidence

Theorem: Let

$$m : \; y = X\beta + \varepsilon, \; \varepsilon \sim \mathcal{N}(0, \sigma^2 V) \tag{1}$$

be a linear regression model ($\rightarrow$ Definition III/1.3.1) with measured $n \times 1$ data vector y, known $n \times p$ design matrix X, known $n \times n$ covariance structure V as well as unknown $p \times 1$ regression coefficients β and unknown noise variance σ^2. Moreover, assume a normal-gamma prior distribution ($\rightarrow$ Proof III/1.4.1) over the model parameters β and $\tau = 1/\sigma^2$:

$$p(\beta, \tau) = \mathcal{N}(\beta; \mu_0, (\tau\Lambda_0)^{-1}) \cdot \text{Gam}(\tau; a_0, b_0) . \tag{2}$$

Then, the log model evidence ($\rightarrow$ Definition IV/3.1.1) for this model is

$$\log p(y|m) = \frac{1}{2}\log|P| - \frac{n}{2}\log(2\pi) + \frac{1}{2}\log|\Lambda_0| - \frac{1}{2}\log|\Lambda_n| + \\ \log\Gamma(a_n) - \log\Gamma(a_0) + a_0\log b_0 - a_n\log b_n \tag{3}$$

where the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$\begin{aligned}
\mu_n &= \Lambda_n^{-1}(X^{\mathrm{T}}Py + \Lambda_0\mu_0) \\
\Lambda_n &= X^{\mathrm{T}}PX + \Lambda_0 \\
a_n &= a_0 + \frac{n}{2} \\
b_n &= b_0 + \frac{1}{2}(y^{\mathrm{T}}Py + \mu_0^{\mathrm{T}}\Lambda_0\mu_0 - \mu_n^{\mathrm{T}}\Lambda_n\mu_n) .
\end{aligned} \tag{4}$$

Proof: According to the law of marginal probability ($\rightarrow$ Definition I/1.2.3), the model evidence ($\rightarrow$ Definition I/5.1.9) for this model is:

$$p(y|m) = \iint p(y|\beta, \tau) \, p(\beta, \tau) \, \mathrm{d}\beta \, \mathrm{d}\tau . \tag{5}$$

According to the law of conditional probability ($\to$ Definition I/1.2.4), the integrand is equivalent to the joint likelihood ($\to$ Definition I/5.1.5):

$$p(y|m) = \iint p(y, \beta, \tau) \, \mathrm{d}\beta \, \mathrm{d}\tau \; . \tag{6}$$

Equation (1) implies the following likelihood function ($\to$ Definition I/5.1.2)

$$p(y|\beta, \sigma^2) = \mathcal{N}(y; X\beta, \sigma^2 V) = \sqrt{\frac{1}{(2\pi)^n |\sigma^2 V|}} \, \exp\left[-\frac{1}{2\sigma^2}(y - X\beta)^{\mathrm{T}} V^{-1}(y - X\beta)\right] \tag{7}$$

which, for mathematical convenience, can also be parametrized as

$$p(y|\beta, \tau) = \mathcal{N}(y; X\beta, (\tau P)^{-1}) = \sqrt{\frac{|\tau P|}{(2\pi)^n}} \, \exp\left[-\frac{\tau}{2}(y - X\beta)^{\mathrm{T}} P(y - X\beta)\right] \tag{8}$$

using the noise precision $\tau = 1/\sigma^2$ and the $n \times n$ precision matrix $P = V^{-1}$.

When deriving the posterior distribution ($\to$ Proof III/1.4.2) $p(\beta, \tau|y)$, the joint likelihood $p(y, \beta, \tau)$ is obtained as

$$\begin{aligned}
p(y, \beta, \tau) = &\sqrt{\frac{\tau^n |P|}{(2\pi)^n}} \sqrt{\frac{\tau^p |\Lambda_0|}{(2\pi)^p}} \frac{b_0^{a_0}}{\Gamma(a_0)} \tau^{a_0 - 1} \exp[-b_0 \tau] \cdot \\
&\exp\left[-\frac{\tau}{2}\left((\beta - \mu_n)^T \Lambda_n (\beta - \mu_n) + (y^T P y + \mu_0^T \Lambda_0 \mu_0 - \mu_n^T \Lambda_n \mu_n)\right)\right] \; .
\end{aligned} \tag{9}$$

Using the probability density function of the multivariate normal distribution ($\to$ Proof II/4.1.2), we can rewrite this as

$$\begin{aligned}
p(y, \beta, \tau) = &\sqrt{\frac{\tau^n |P|}{(2\pi)^n}} \sqrt{\frac{\tau^p |\Lambda_0|}{(2\pi)^p}} \sqrt{\frac{(2\pi)^p}{\tau^p |\Lambda_n|}} \frac{b_0^{a_0}}{\Gamma(a_0)} \tau^{a_0 - 1} \exp[-b_0 \tau] \cdot \\
&\mathcal{N}(\beta; \mu_n, (\tau \Lambda_n)^{-1}) \, \exp\left[-\frac{\tau}{2}(y^T P y + \mu_0^T \Lambda_0 \mu_0 - \mu_n^T \Lambda_n \mu_n)\right] \; .
\end{aligned} \tag{10}$$

Now, β can be integrated out easily:

$$\begin{aligned}
\int p(y, \beta, \tau) \, \mathrm{d}\beta = &\sqrt{\frac{\tau^n |P|}{(2\pi)^n}} \sqrt{\frac{|\Lambda_0|}{|\Lambda_n|}} \frac{b_0^{a_0}}{\Gamma(a_0)} \tau^{a_0 - 1} \exp[-b_0 \tau] \cdot \\
&\exp\left[-\frac{\tau}{2}(y^T P y + \mu_0^T \Lambda_0 \mu_0 - \mu_n^T \Lambda_n \mu_n)\right] \; .
\end{aligned} \tag{11}$$

Using the probability density function of the gamma distribution ($\to$ Proof II/3.4.5), we can rewrite this as

$$\int p(y, \beta, \tau) \, \mathrm{d}\beta = \sqrt{\frac{|P|}{(2\pi)^n}} \sqrt{\frac{|\Lambda_0|}{|\Lambda_n|}} \frac{b_0^{a_0}}{\Gamma(a_0)} \frac{\Gamma(a_n)}{b_n^{a_n}} \mathrm{Gam}(\tau; a_n, b_n) \; . \tag{12}$$

Finally, τ can also be integrated out:

$$\iint p(y, \beta, \tau) \, \mathrm{d}\beta \, \mathrm{d}\tau = \sqrt{\frac{|P|}{(2\pi)^n}} \sqrt{\frac{|\Lambda_0|}{|\Lambda_n|}} \frac{\Gamma(a_n)}{\Gamma(a_0)} \frac{b_0^{a_0}}{b_n^{a_n}} = p(y|m) \; . \tag{13}$$

Thus, the log model evidence ($\rightarrow$ Definition IV/3.1.1) of this model is given by

$$\begin{aligned}
\log p(y|m) = & \frac{1}{2} \log |P| - \frac{n}{2} \log(2\pi) + \frac{1}{2} \log |\Lambda_0| - \frac{1}{2} \log |\Lambda_n| + \\
& \log \Gamma(a_n) - \log \Gamma(a_0) + a_0 \log b_0 - a_n \log b_n \; .
\end{aligned} \tag{14}$$

1.4.4 Posterior probability of alternative hypothesis

Theorem: Let there be a linear regression model ($\rightarrow$ Definition III/1.3.1) with normally distributed ($\rightarrow$ Definition II/4.1.1) errors:

$$y = X\beta + \varepsilon, \; \varepsilon \sim \mathcal{N}(0, \sigma^2 V) \tag{1}$$

and assume a normal-gamma ($\rightarrow$ Definition II/4.3.1) prior distribution ($\rightarrow$ Definition I/5.1.3) over the model parameters β and $\tau = 1/\sigma^2$:

$$p(\beta, \tau) = \mathcal{N}(\beta; \mu_0, (\tau\Lambda_0)^{-1}) \cdot \mathrm{Gam}(\tau; a_0, b_0) \; . \tag{2}$$

Then, the posterior ($\rightarrow$ Definition I/5.1.7) probability ($\rightarrow$ Definition I/1.2.1) of the alternative hypothesis ($\rightarrow$ Definition I/4.3.3)

$$\mathrm{H}_1 : \; c^{\mathrm{T}}\beta > 0 \tag{3}$$

is given by

$$\Pr(\mathrm{H}_1|y) = 1 - \mathrm{T}\left(-\frac{c^{\mathrm{T}}\mu}{\sqrt{c^{\mathrm{T}}\Sigma c}}; \nu\right) \tag{4}$$

where c is a $p \times 1$ contrast vector ($\rightarrow$ Definition "con"), $\mathrm{T}(x; \nu)$ is the cumulative distribution function ($\rightarrow$ Definition I/1.4.8) of the t-distribution ($\rightarrow$ Definition II/3.3.1) with ν degrees of freedom ($\rightarrow$ Definition "dof") and μ, Σ and ν can be obtained from the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) of Bayesian linear regression.

Proof: The posterior distribution for Bayesian linear regression ($\rightarrow$ Proof III/1.4.2) is given by a normal-gamma distribution ($\rightarrow$ Definition II/4.3.1) over β and $\tau = 1/\sigma^2$

$$p(\beta, \tau|y) = \mathcal{N}(\beta; \mu_n, (\tau\Lambda_n)^{-1}) \cdot \mathrm{Gam}(\tau; a_n, b_n) \tag{5}$$

with the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7)

$$\mu_n = \Lambda_n^{-1}(X^{\mathrm{T}}Py + \Lambda_0\mu_0)$$
$$\Lambda_n = X^{\mathrm{T}}PX + \Lambda_0$$
$$a_n = a_0 + \frac{n}{2} \tag{6}$$
$$b_n = b_0 + \frac{1}{2}(y^{\mathrm{T}}Py + \mu_0^{\mathrm{T}}\Lambda_0\mu_0 - \mu_n^{\mathrm{T}}\Lambda_n\mu_n) \ .$$

The marginal distribution of a normal-gamma distribution is a multivariate t-distribution ($\to$ Proof II/4.3.4), such that the marginal ($\to$ Definition I/1.3.3) posterior ($\to$ Definition I/5.1.7) distribution of β is

$$p(\beta|y) = \mathrm{t}(\beta; \mu, \Sigma, \nu) \tag{7}$$

with the posterior hyperparameters ($\to$ Definition I/5.1.7)

$$\mu = \mu_n$$
$$\Sigma = \left(\frac{a_n}{b_n}\Lambda_n\right)^{-1} \tag{8}$$
$$\nu = 2\, a_n \ .$$

Define the quantity $\gamma = c^{\mathrm{T}}\beta$. According to the linear transformation theorem for the multivariate t-distribution ($\to$ Proof "mvt-ltt"), γ also follows a multivariate t-distribution ($\to$ Definition II/4.2.1):

$$p(\gamma|y) = \mathrm{t}(\gamma; c^{\mathrm{T}}\mu, c^{\mathrm{T}}\Sigma\, c, \nu) \ . \tag{9}$$

Because c^{T} is a $1 \times p$ vector, γ is a scalar and actually has a non-central scaled t-distribution ($\to$ Definition "ncst"). Therefore, the posterior probability of H_1 can be calculated using a one-dimensional integral:

$$\begin{aligned}
\Pr(H_1|y) &= p(\gamma > 0|y) \\
&= \int_0^{+\infty} p(\gamma|y)\,\mathrm{d}\gamma \\
&= 1 - \int_{-\infty}^0 p(\gamma|y)\,\mathrm{d}\gamma \\
&= 1 - \mathrm{T}_{\mathrm{ncst}}(0; c^{\mathrm{T}}\mu, c^{\mathrm{T}}\Sigma\, c, \nu) \ .
\end{aligned} \tag{10}$$

Using the relation between non-central scaled t-distribution and standard t-distribution ($\to$ Proof "ncst-t"), we can finally write:

$$\begin{aligned}
\Pr(H_1|y) &= 1 - \mathrm{T}\left(\frac{(0 - c^{\mathrm{T}}\mu)}{\sqrt{c^{\mathrm{T}}\Sigma c}}; \nu\right) \\
&= 1 - \mathrm{T}\left(-\frac{c^{\mathrm{T}}\mu}{\sqrt{c^{\mathrm{T}}\Sigma c}}; \nu\right) \ .
\end{aligned} \tag{11}$$

- Koch, Karl-Rudolf (2007): "Multivariate t-distribution"; in: *Introduction to Bayesian Statistics*, Springer, Berlin/Heidelberg, 2007, eqs. 2.235, 2.236, 2.213, 2.210, 2.188; URL: https://www.springer.com/de/book/9783540727231; DOI: 10.1007/978-3-540-72726-2.

1.4.5 Posterior credibility region excluding null hypothesis

Theorem: Let there be a linear regression model ($\to$ Definition III/1.3.1) with normally distributed ($\to$ Definition II/4.1.1) errors:

$$y = X\beta + \varepsilon, \ \varepsilon \sim \mathcal{N}(0, \sigma^2 V) \tag{1}$$

and assume a normal-gamma ($\to$ Definition II/4.3.1) prior distribution ($\to$ Definition I/5.1.3) over the model parameters β and $\tau = 1/\sigma^2$:

$$p(\beta, \tau) = \mathcal{N}(\beta; \mu_0, (\tau\Lambda_0)^{-1}) \cdot \mathrm{Gam}(\tau; a_0, b_0) . \tag{2}$$

Then, the largest posterior ($\to$ Definition I/5.1.7) credibility region ($\to$ Definition "cr") that does not contain the omnibus null hypothesis ($\to$ Definition I/4.3.2)

$$\mathrm{H}_0 : \ C^{\mathrm{T}}\beta = 0 \tag{3}$$

is given by the credibility level ($\to$ Definition "cr")

$$(1 - \alpha) = \mathrm{F}\left(\left[\mu^{\mathrm{T}}C(C^{\mathrm{T}}\Sigma\, C)^{-1}C^{\mathrm{T}}\mu\right]/q; q, \nu\right) \tag{4}$$

where C is a $p \times q$ contrast matrix ($\to$ Definition "con"), $\mathrm{F}(x; v, w)$ is the cumulative distribution function ($\to$ Definition I/1.4.8) of the F-distribution ($\to$ Definition II/3.7.1) with v numerator degrees of freedom ($\to$ Definition "dof"), w denominator degrees of freedom ($\to$ Definition "dof") and μ, Σ and ν can be obtained from the posterior hyperparameters ($\to$ Definition I/5.1.7) of Bayesian linear regression.

Proof: The posterior distribution for Bayesian linear regression ($\to$ Proof III/1.4.2) is given by a normal-gamma distribution ($\to$ Definition II/4.3.1) over β and $\tau = 1/\sigma^2$

$$p(\beta, \tau | y) = \mathcal{N}(\beta; \mu_n, (\tau\Lambda_n)^{-1}) \cdot \mathrm{Gam}(\tau; a_n, b_n) \tag{5}$$

with the posterior hyperparameters ($\to$ Definition I/5.1.7)

$$\begin{aligned}
\mu_n &= \Lambda_n^{-1}(X^{\mathrm{T}}Py + \Lambda_0\mu_0) \\
\Lambda_n &= X^{\mathrm{T}}PX + \Lambda_0 \\
a_n &= a_0 + \frac{n}{2} \\
b_n &= b_0 + \frac{1}{2}(y^{\mathrm{T}}Py + \mu_0^{\mathrm{T}}\Lambda_0\mu_0 - \mu_n^{\mathrm{T}}\Lambda_n\mu_n) .
\end{aligned} \tag{6}$$

The marginal distribution of a normal-gamma distribution is a multivariate t-distribution ($\to$ Proof II/4.3.4), such that the marginal ($\to$ Definition I/1.3.3) posterior ($\to$ Definition I/5.1.7) distribution of β is

$$p(\beta|y) = \mathrm{t}(\beta; \mu, \Sigma, \nu) \tag{7}$$

with the posterior hyperparameters ($\to$ Definition I/5.1.7)

$$
\begin{aligned}
\mu &= \mu_n \\
\Sigma &= \left(\frac{a_n}{b_n}\Lambda_n\right)^{-1} \\
\nu &= 2\,a_n \;.
\end{aligned}
\tag{8}
$$

Define the quantity $\gamma = C^\mathrm{T}\beta$. According to the linear transformation theorem for the multivariate t-distribution ($\to$ Proof "mvt-ltt"), γ also follows a multivariate t-distribution ($\to$ Definition II/4.2.1):

$$p(\gamma|y) = \mathrm{t}(\gamma; C^\mathrm{T}\mu, C^\mathrm{T}\Sigma\,C, \nu) \;. \tag{9}$$

Because C^T is a $q \times p$ matrix, γ is a $q \times 1$ vector. The quadratic form of a multivariate t-distributed random variable has an F-distribution ($\to$ Proof "mvt-f"), such that we can write:

$$\mathrm{QF}(\gamma) = (\gamma - C^\mathrm{T}\mu)^\mathrm{T}(C^\mathrm{T}\Sigma\,C)^{-1}(\gamma - C^\mathrm{T}\mu)/q \sim \mathrm{F}(q, \nu) \;. \tag{10}$$

Therefore, the largest posterior credibility region for γ which does not contain $\gamma = 0_q$ (i.e. only touches this origin point) can be obtained by plugging $\mathrm{QF}(0)$ into the cumulative distribution function of the F-distribution:

$$
\begin{aligned}
(1 - \alpha) &= \mathrm{F}\left(\mathrm{QF}(0); q, \nu\right) \\
&= \mathrm{F}\left(\left[\mu^\mathrm{T}C(C^\mathrm{T}\Sigma\,C)^{-1}C^\mathrm{T}\mu\right]/q; q, \nu\right) \;.
\end{aligned}
\tag{11}
$$

2 Multivariate normal data

2.1 General linear model

2.1.1 Definition

Definition: Let Y be an $n \times v$ matrix and let X be an $n \times p$ matrix. Then, a statement asserting a linear mapping from X to Y with parameters B and matrix-normally distributed ($\rightarrow$ Definition II/5.1.1) errors E

$$Y = XB + E, \; E \sim \mathcal{MN}(0, V, \Sigma) \tag{1}$$

is called a multivariate linear regression model or simply, "general linear model".
- Y is called "data matrix", "set of dependent variables" or "measurements";
- X is called "design matrix", "set of independent variables" or "predictors";
- B are called "regression coefficients" or "weights";
- E is called "noise matrix" or "error terms";
- V is called "covariance across rows";
- Σ is called "covariance across columns";
- n is the number of observations;
- v is the number of measurements;
- p is the number of predictors.

When rows of Y correspond to units of time, e.g. subsequent measurements, V is called "temporal covariance". When columns of Y correspond to units of space, e.g. measurement channels, Σ is called "spatial covariance".

When the covariance matrix V is a scalar multiple of the $n \times n$ identity matrix, this is called a general linear model with independent and identically distributed (i.i.d.) observations:

$$V = \lambda I_n \quad \Rightarrow \quad E \sim \mathcal{MN}(0, \lambda I_n, \Sigma) \quad \Rightarrow \quad \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \lambda \Sigma) \; . \tag{2}$$

Otherwise, it is called a general linear model with correlated observations.

2.1.2 Ordinary least squares

Theorem: Given a general linear model ($\rightarrow$ Definition III/2.1.1) with independent observations

$$Y = XB + E, \; E \sim \mathcal{MN}(0, \sigma^2 I_n, \Sigma) \; , \tag{1}$$

the ordinary least squares ($\rightarrow$ Proof III/1.3.2) parameters estimates are given by

$$\hat{B} = (X^{\mathrm{T}} X)^{-1} X^{\mathrm{T}} Y \; . \tag{2}$$

Proof: Let $\hat{B}$ be the ordinary least squares ($\rightarrow$ Proof III/1.3.2) (OLS) solution and let $\hat{E} = Y - X\hat{B}$ be the resulting matrix of residuals. According to the exogeneity assumption of OLS, the errors have conditional mean ($\rightarrow$ Definition I/1.5.1) zero

$$\mathrm{E}(E|X) = 0 \ , \tag{3}$$

a direct consequence of which is that the regressors are uncorrelated with the errors

$$\mathrm{E}(X^{\mathrm{T}}E) = 0 \ , \tag{4}$$

which, in the finite sample, means that the residual matrix must be orthogonal to the design matrix:

$$X^{\mathrm{T}}\hat{E} = 0 \ . \tag{5}$$

From (5), the OLS formula can be directly derived:

$$
\begin{aligned}
X^{\mathrm{T}}\hat{E} &= 0 \\
X^{\mathrm{T}}\left(Y - X\hat{B}\right) &= 0 \\
X^{\mathrm{T}}Y - X^{\mathrm{T}}X\hat{B} &= 0 \\
X^{\mathrm{T}}X\hat{B} &= X^{\mathrm{T}}Y \\
\hat{B} &= (X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}}Y \ .
\end{aligned}
\tag{6}
$$

2.1.3 Weighted least squares

Theorem: Given a general linear model ($\to$ Definition III/2.1.1) with correlated observations

$$Y = XB + E, \ E \sim \mathcal{MN}(0, V, \Sigma) \ , \tag{1}$$

the weighted least sqaures ($\to$ Proof III/1.3.13) parameter estimates are given by

$$\hat{B} = (X^{\mathrm{T}}V^{-1}X)^{-1}X^{\mathrm{T}}V^{-1}Y \ . \tag{2}$$

Proof: Let there be an $n \times n$ square matrix W, such that

$$WVW^{\mathrm{T}} = I_n \ . \tag{3}$$

Since V is a covariance matrix and thus symmetric, W is also symmetric and can be expressed as the matrix square root of the inverse of V:

$$WW = V^{-1} \quad \Leftrightarrow \quad W = V^{-1/2} \ . \tag{4}$$

Left-multiplying the linear regression equation (1) with W, the linear transformation theorem ($\to$ Proof II/5.1.5) implies that

$$WY = WXB + WE, \ WE \sim \mathcal{MN}(0, WVW^{\mathrm{T}}, \Sigma) \ . \tag{5}$$

Applying (3), we see that (5) is actually a general linear model ($\rightarrow$ Definition III/2.1.1) with independent observations

$$\tilde{Y} = \tilde{X}B + \tilde{E}, \ \tilde{E} \sim \mathcal{N}(0, I_n, \Sigma) \tag{6}$$

where $\tilde{Y} = WY$, $\tilde{X} = WX$ and $\tilde{E} = WE$, such that we can apply the ordinary least squares solution ($\rightarrow$ Proof III/2.1.2) giving

$$
\begin{aligned}
\hat{B} &= (\tilde{X}^\mathrm{T}\tilde{X})^{-1}\tilde{X}^\mathrm{T}\tilde{Y} \\
&= \left((WX)^\mathrm{T}WX\right)^{-1}(WX)^\mathrm{T}WY \\
&= \left(X^\mathrm{T}W^\mathrm{T}WX\right)^{-1}X^\mathrm{T}W^\mathrm{T}WY \\
&= \left(X^\mathrm{T}WWX\right)^{-1}X^\mathrm{T}WWY \\
&\overset{(4)}{=} \left(X^\mathrm{T}V^{-1}X\right)^{-1}X^\mathrm{T}V^{-1}Y
\end{aligned}
\tag{7}
$$

which corresponds to the weighted least squares solution (2).

2.1.4 Maximum likelihood estimation

Theorem: Given a general linear model ($\rightarrow$ Definition III/2.1.1) with matrix-normally distributed ($\rightarrow$ Definition II/5.1.1) errors

$$Y = XB + E, \ E \sim \mathcal{MN}(0, V, \Sigma) \, , \tag{1}$$

maximum likelihood estimates ($\rightarrow$ Definition I/4.1.3) for the unknown parameters B and Σ are given by

$$
\begin{aligned}
\hat{B} &= (X^\mathrm{T}V^{-1}X)^{-1}X^\mathrm{T}V^{-1}Y \\
\hat{\Sigma} &= \frac{1}{n}(Y - X\hat{B})^\mathrm{T}V^{-1}(Y - X\hat{B}) \, .
\end{aligned}
\tag{2}
$$

Proof: In (1), Y is an $n \times v$ matrix of measurements (n observations, v dependent variables), X is an $n \times p$ design matrix (n observations, p independent variables) and V is an $n \times n$ covariance matrix across observations. This multivariate GLM implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$
\begin{aligned}
p(Y|B, \Sigma) &= \mathcal{MN}(Y; XB, V, \Sigma) \\
&= \sqrt{\frac{1}{(2\pi)^{nv}|\Sigma|^n|V|^v}} \cdot \exp\left[-\frac{1}{2}\mathrm{tr}\left(\Sigma^{-1}(Y - XB)^\mathrm{T}V^{-1}(Y - XB)\right)\right]
\end{aligned}
\tag{3}
$$

and the log-likelihood function ($\rightarrow$ Definition I/4.1.2)

$$
\begin{aligned}
\mathrm{LL}(B, \Sigma) &= \log p(Y|B, \Sigma) \\
&= -\frac{nv}{2} \log(2\pi) - \frac{n}{2} \log |\Sigma| - \frac{v}{2} \log |V| \\
&\quad - \frac{1}{2} \operatorname{tr}\left[\Sigma^{-1}(Y - XB)^{\mathrm{T}} V^{-1}(Y - XB)\right] \ .
\end{aligned}
\tag{4}
$$

Substituting V^{-1} by the precision matrix P to ease notation, we have:

$$
\begin{aligned}
\mathrm{LL}(B, \Sigma) &= -\frac{nv}{2} \log(2\pi) - \frac{n}{2} \log(|\Sigma|) - \frac{v}{2} \log(|V|) \\
&\quad - \frac{1}{2} \operatorname{tr}\left[\Sigma^{-1}\left(Y^{\mathrm{T}} PY - Y^{\mathrm{T}} PXB - B^{\mathrm{T}} X^{\mathrm{T}} PY + B^{\mathrm{T}} X^{\mathrm{T}} PXB\right)\right] \ .
\end{aligned}
\tag{5}
$$

The derivative of the log-likelihood function (5) with respect to B is

$$
\begin{aligned}
\frac{\mathrm{dLL}(B, \Sigma)}{\mathrm{d}B} &= \frac{\mathrm{d}}{\mathrm{d}B}\left(-\frac{1}{2} \operatorname{tr}\left[\Sigma^{-1}\left(Y^{\mathrm{T}} PY - Y^{\mathrm{T}} PXB - B^{\mathrm{T}} X^{\mathrm{T}} PY + B^{\mathrm{T}} X^{\mathrm{T}} PXB\right)\right]\right) \\
&= \frac{\mathrm{d}}{\mathrm{d}B}\left(-\frac{1}{2} \operatorname{tr}\left[-2\Sigma^{-1} Y^{\mathrm{T}} PXB\right]\right) + \frac{\mathrm{d}}{\mathrm{d}B}\left(-\frac{1}{2} \operatorname{tr}\left[\Sigma^{-1} B^{\mathrm{T}} X^{\mathrm{T}} PXB\right]\right) \\
&= -\frac{1}{2}\left(-2X^{\mathrm{T}} PY\Sigma^{-1}\right) - \frac{1}{2}\left(X^{\mathrm{T}} PXB\Sigma^{-1} + (X^{\mathrm{T}} PX)^{\mathrm{T}} B(\Sigma^{-1})^{\mathrm{T}}\right) \\
&= X^{\mathrm{T}} PY\Sigma^{-1} - X^{\mathrm{T}} PXB\Sigma^{-1}
\end{aligned}
\tag{6}
$$

and setting this derivative to zero gives the MLE for B:

$$
\begin{aligned}
\frac{\mathrm{dLL}(\hat{B}, \Sigma)}{\mathrm{d}B} &= 0 \\
0 &= X^{\mathrm{T}} PY\Sigma^{-1} - X^{\mathrm{T}} PX\hat{B}\Sigma^{-1} \\
0 &= X^{\mathrm{T}} PY - X^{\mathrm{T}} PX\hat{B} \\
X^{\mathrm{T}} PX\hat{B} &= X^{\mathrm{T}} PY \\
\hat{B} &= \left(X^{\mathrm{T}} PX\right)^{-1} X^{\mathrm{T}} PY
\end{aligned}
\tag{7}
$$

The derivative of the log-likelihood function (4) at $\hat{B}$ with respect to Σ is

$$
\begin{aligned}
\frac{\mathrm{dLL}(\hat{B}, \Sigma)}{\mathrm{d}\Sigma} &= \frac{\mathrm{d}}{\mathrm{d}\Sigma}\left(-\frac{n}{2} \log |\Sigma| - \frac{1}{2} \operatorname{tr}\left[\Sigma^{-1}(Y - X\hat{B})^{\mathrm{T}} V^{-1}(Y - X\hat{B})\right]\right) \\
&= -\frac{n}{2}\left(\Sigma^{-1}\right)^{\mathrm{T}} + \frac{1}{2}\left(\Sigma^{-1}(Y - X\hat{B})^{\mathrm{T}} V^{-1}(Y - X\hat{B})\Sigma^{-1}\right)^{\mathrm{T}} \\
&= -\frac{n}{2} \Sigma^{-1} + \frac{1}{2} \Sigma^{-1}(Y - X\hat{B})^{\mathrm{T}} V^{-1}(Y - X\hat{B})\Sigma^{-1}
\end{aligned}
\tag{8}
$$

and setting this derivative to zero gives the MLE for Σ:

$$\frac{\mathrm{dLL}(\hat{B}, \hat{\Sigma})}{\mathrm{d}\Sigma} = 0$$

$$0 = -\frac{n}{2}\hat{\Sigma}^{-1} + \frac{1}{2}\hat{\Sigma}^{-1}(Y - X\hat{B})^{\mathrm{T}}V^{-1}(Y - X\hat{B})\hat{\Sigma}^{-1}$$

$$\frac{n}{2}\hat{\Sigma}^{-1} = \frac{1}{2}\hat{\Sigma}^{-1}(Y - X\hat{B})^{\mathrm{T}}V^{-1}(Y - X\hat{B})\hat{\Sigma}^{-1} \tag{9}$$

$$\hat{\Sigma}^{-1} = \frac{1}{n}\hat{\Sigma}^{-1}(Y - X\hat{B})^{\mathrm{T}}V^{-1}(Y - X\hat{B})\hat{\Sigma}^{-1}$$

$$I_v = \frac{1}{n}(Y - X\hat{B})^{\mathrm{T}}V^{-1}(Y - X\hat{B})\hat{\Sigma}^{-1}$$

$$\hat{\Sigma} = \frac{1}{n}(Y - X\hat{B})^{\mathrm{T}}V^{-1}(Y - X\hat{B})$$

Together, (7) and (9) constitute the MLE for the GLM.

2.2 Multivariate Bayesian linear regression

2.2.1 Conjugate prior distribution

Theorem: Let

$$Y = XB + E, \ E \sim \mathcal{MN}(0, V, \Sigma) \tag{1}$$

be a general linear model ($\rightarrow$ Definition III/2.1.1) with measured $n \times v$ data matrix Y, known $n \times p$ design matrix X, known $n \times n$ covariance structure ($\rightarrow$ Definition II/5.1.1) V as well as unknown $p \times v$ regression coefficients B and unknown $v \times v$ noise covariance ($\rightarrow$ Definition II/5.1.1) Σ.
Then, the conjugate prior ($\rightarrow$ Definition I/5.2.5) for this model is a normal-Wishart distribution ($\rightarrow$ Definition "nw")

$$p(B, T) = \mathcal{MN}(B; M_0, \Lambda_0^{-1}, T^{-1}) \cdot \mathcal{W}(T; \Omega_0^{-1}, \nu_0) \tag{2}$$

where $T = \Sigma^{-1}$ is the inverse noise covariance ($\rightarrow$ Definition I/1.7.6) or noise precision matrix ($\rightarrow$ Definition I/1.7.9).

Proof: By definition, a conjugate prior ($\rightarrow$ Definition I/5.2.5) is a prior distribution ($\rightarrow$ Definition I/5.1.3) that, when combined with the likelihood function ($\rightarrow$ Definition I/5.1.2), leads to a posterior distribution ($\rightarrow$ Definition I/5.1.7) that belongs to the same family of probability distributions ($\rightarrow$ Definition I/1.3.1). This is fulfilled when the prior density and the likelihood function are proportional to the model parameters in the same way, i.e. the model parameters appear in the same functional form in both.
Equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$p(Y|B, \Sigma) = \mathcal{MN}(Y; XB, V, \Sigma) = \sqrt{\frac{1}{(2\pi)^{nv}|\Sigma|^n|V|^v}} \exp\left[-\frac{1}{2}\mathrm{tr}\left(\Sigma^{-1}(Y - XB)^{\mathrm{T}}V^{-1}(Y - XB)\right)\right]$$
(3)

which, for mathematical convenience, can also be parametrized as

$$p(Y|B, T) = \mathcal{MN}(Y; XB, P, T^{-1}) = \sqrt{\frac{|T|^n|P|^v}{(2\pi)^{nv}}} \exp\left[-\frac{1}{2}\mathrm{tr}\left(T(Y - XB)^{\mathrm{T}}P(Y - XB)\right)\right] \quad (4)$$

using the $v \times v$ precision matrix ($\rightarrow$ Definition I/1.7.9) $T = \Sigma^{-1}$ and the $n \times n$ precision matrix ($\rightarrow$ Definition I/1.7.9) $P = V^{-1}$.

Seperating constant and variable terms, we have:

$$p(Y|B, T) = \sqrt{\frac{|P|^v}{(2\pi)^{nv}}} \cdot |T|^{n/2} \cdot \exp\left[-\frac{1}{2}\mathrm{tr}\left(T(Y - XB)^{\mathrm{T}}P(Y - XB)\right)\right] . \quad (5)$$

Expanding the product in the exponent, we have:

$$p(Y|B, T) = \sqrt{\frac{|P|^v}{(2\pi)^{nv}}} \cdot |T|^{n/2} \cdot \exp\left[-\frac{1}{2}\mathrm{tr}\left(T\left[Y^{\mathrm{T}}PY - Y^{\mathrm{T}}PXB - B^{\mathrm{T}}X^{\mathrm{T}}PY + B^{\mathrm{T}}X^{\mathrm{T}}PXB\right]\right)\right] .$$
(6)

Completing the square over β, finally gives

$$p(Y|B, T) = \sqrt{\frac{|P|^v}{(2\pi)^{nv}}} \cdot |T|^{n/2} \cdot \exp\left[-\frac{1}{2}\mathrm{tr}\left(T\left[(B - \tilde{X}Y)^{\mathrm{T}}X^{\mathrm{T}}PX(B - \tilde{X}Y) - Y^{\mathrm{T}}QY + Y^{\mathrm{T}}PY\right]\right)\right]$$
(7)

where $\tilde{X} = \left(X^{\mathrm{T}}PX\right)^{-1}X^{\mathrm{T}}P$ and $Q = \tilde{X}^{\mathrm{T}}\left(X^{\mathrm{T}}PX\right)\tilde{X}$.

In other words, the likelihood function ($\rightarrow$ Definition I/5.1.2) is proportional to a power of the determinant of T, times an exponential of the trace of T and an exponential of the trace of a squared form of B, weighted by T:

$$p(Y|B, T) \propto |T|^{n/2} \cdot \exp\left[-\frac{1}{2}\mathrm{tr}\left(T\left[Y^{\mathrm{T}}PY - Y^{\mathrm{T}}QY\right]\right)\right] \cdot \exp\left[-\frac{1}{2}\mathrm{tr}\left(T\left[(B - \tilde{X}Y)^{\mathrm{T}}X^{\mathrm{T}}PX(B - \tilde{X}Y)\right]\right)\right] .$$
(8)

The same is true for a normal-Wishart distribution ($\rightarrow$ Definition "nw") over B and T

$$p(B, T) = \mathcal{MN}(B; M_0, \Lambda_0^{-1}, T^{-1}) \cdot \mathcal{W}(T; \Omega_0^{-1}, \nu_0) \quad (9)$$

the probability density function of which ($\rightarrow$ Proof "nw-pdf")

$$p(B, T) = \sqrt{\frac{|T|^p|\Lambda_0|^v}{(2\pi)^{pv}}} \exp\left[-\frac{1}{2}\mathrm{tr}\left(T(B - M_0)^{\mathrm{T}}\Lambda_0(B - M_0)\right)\right] \cdot \frac{1}{\Gamma_v\left(\frac{\nu_0}{2}\right)}\sqrt{\frac{|\Omega_0|^{\nu_0}}{2^{\nu_0 v}}}|T|^{(\nu_0 - v - 1)/2}\exp\left[-\frac{1}{2}\mathrm{tr}\left(\Omega_0 T\right)\right]$$
(10)

exhibits the same proportionality

$$p(B, T) \propto |T|^{(\nu_0 + p - v - 1)/2} \cdot \exp\left[-\frac{1}{2}\mathrm{tr}\left(T\Omega_0\right)\right] \cdot \exp\left[-\frac{1}{2}\mathrm{tr}\left(T\left[(B - M_0)^{\mathrm{T}}\Lambda_0(B - M_0)\right]\right)\right] \quad (11)$$

and is therefore conjugate relative to the likelihood.

2.2.2 Posterior distribution

Theorem: Let

$$Y = XB + E, \; E \sim \mathcal{MN}(0, V, \Sigma) \tag{1}$$

be a general linear model ($\to$ Definition III/2.1.1) with measured $n \times v$ data matrix Y, known $n \times p$ design matrix X, known $n \times n$ covariance structure ($\to$ Definition II/5.1.1) V as well as unknown $p \times v$ regression coefficients B and unknown $v \times v$ noise covariance ($\to$ Definition II/5.1.1) Σ. Moreover, assume a normal-Wishart prior distribution ($\to$ Proof III/2.2.1) over the model parameters B and $T = \Sigma^{-1}$:

$$p(B, T) = \mathcal{MN}(B; M_0, \Lambda_0^{-1}, T^{-1}) \cdot \mathcal{W}(T; \Omega_0^{-1}, \nu_0) \, . \tag{2}$$

Then, the posterior distribution ($\to$ Definition I/5.1.7) is also a normal-Wishart distribution ($\to$ Definition "nw")

$$p(B, T|Y) = \mathcal{MN}(B; M_n, \Lambda_n^{-1}, T^{-1}) \cdot \mathcal{W}(T; \Omega_n^{-1}, \nu_n) \tag{3}$$

and the posterior hyperparameters ($\to$ Definition I/5.1.7) are given by

$$
\begin{aligned}
M_n &= \Lambda_n^{-1}(X^{\mathrm{T}}PY + \Lambda_0 M_0) \\
\Lambda_n &= X^{\mathrm{T}}PX + \Lambda_0 \\
\Omega_n &= \Omega_0 + Y^{\mathrm{T}}PY + M_0^{\mathrm{T}}\Lambda_0 M_0 - M_n^{\mathrm{T}}\Lambda_n M_n \\
\nu_n &= \nu_0 + n \, .
\end{aligned}
\tag{4}
$$

Proof: According to Bayes' theorem ($\to$ Proof I/5.3.1), the posterior distribution ($\to$ Definition I/5.1.7) is given by

$$p(B, T|Y) = \frac{p(Y|B, T)\, p(B, T)}{p(Y)} \, . \tag{5}$$

Since $p(Y)$ is just a normalization factor, the posterior is proportional ($\to$ Proof I/5.1.8) to the numerator:

$$p(B, T|Y) \propto p(Y|B, T)\, p(B, T) = p(Y, B, T) \ . \tag{6}$$

Equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$p(Y|B, \Sigma) = \mathcal{MN}(Y; XB, V, \Sigma) = \sqrt{\frac{1}{(2\pi)^{nv}|\Sigma|^n|V|^v}}\, \exp\left[-\frac{1}{2}\mathrm{tr}\left(\Sigma^{-1}(Y - XB)^{\mathrm{T}}V^{-1}(Y - XB)\right)\right] \tag{7}$$

which, for mathematical convenience, can also be parametrized as

$$p(Y|B, T) = \mathcal{MN}(Y; XB, P, T^{-1}) = \sqrt{\frac{|T|^n|P|^v}{(2\pi)^{nv}}}\, \exp\left[-\frac{1}{2}\mathrm{tr}\left(T(Y - XB)^{\mathrm{T}}P(Y - XB)\right)\right] \tag{8}$$

using the $v \times v$ precision matrix ($\rightarrow$ Definition I/1.7.9) $T = \Sigma^{-1}$ and the $n \times n$ precision matrix ($\rightarrow$ Definition I/1.7.9) $P = V^{-1}$.

Combining the likelihood function ($\rightarrow$ Definition I/5.1.2) (8) with the prior distribution ($\rightarrow$ Definition I/5.1.3) (2), the joint likelihood ($\rightarrow$ Definition I/5.1.5) of the model is given by

$$\begin{aligned}
p(Y, B, T) &= p(Y|B, T)\, p(B, T) \\
&= \sqrt{\frac{|T|^n|P|^v}{(2\pi)^{nv}}}\, \exp\left[-\frac{1}{2}\mathrm{tr}\left(T(Y - XB)^{\mathrm{T}}P(Y - XB)\right)\right] \cdot \\
&\quad \sqrt{\frac{|T|^p|\Lambda_0|^v}{(2\pi)^{pv}}}\, \exp\left[-\frac{1}{2}\mathrm{tr}\left(T(B - M_0)^{\mathrm{T}}\Lambda_0(B - M_0)\right)\right] \cdot \\
&\quad \frac{1}{\Gamma_v\left(\frac{\nu_0}{2}\right)}\sqrt{\frac{|\Omega_0|^{\nu_0}}{2^{\nu_0 v}}}|T|^{(\nu_0 - v - 1)/2}\, \exp\left[-\frac{1}{2}\mathrm{tr}\left(\Omega_0 T\right)\right] \ .
\end{aligned} \tag{9}$$

Collecting identical variables gives:

$$\begin{aligned}
p(Y, B, T) &= \sqrt{\frac{|T|^n|P|^v}{(2\pi)^{nv}}}\sqrt{\frac{|T|^p|\Lambda_0|^v}{(2\pi)^{pv}}}\sqrt{\frac{|\Omega_0|^{\nu_0}}{2^{\nu_0 v}}}\frac{1}{\Gamma_v\left(\frac{\nu_0}{2}\right)} \cdot |T|^{(\nu_0 - v - 1)/2}\, \exp\left[-\frac{1}{2}\mathrm{tr}\left(\Omega_0 T\right)\right] \cdot \\
&\quad \exp\left[-\frac{1}{2}\mathrm{tr}\left(T\left[(Y - XB)^{\mathrm{T}}P(Y - XB) + (B - M_0)^{\mathrm{T}}\Lambda_0(B - M_0)\right]\right)\right] \ .
\end{aligned} \tag{10}$$

Expanding the products in the exponent gives:

$$\begin{aligned}
p(Y, B, T) &= \sqrt{\frac{|T|^n|P|^v}{(2\pi)^{nv}}}\sqrt{\frac{|T|^p|\Lambda_0|^v}{(2\pi)^{pv}}}\sqrt{\frac{|\Omega_0|^{\nu_0}}{2^{\nu_0 v}}}\frac{1}{\Gamma_v\left(\frac{\nu_0}{2}\right)} \cdot |T|^{(\nu_0 - v - 1)/2}\, \exp\left[-\frac{1}{2}\mathrm{tr}\left(\Omega_0 T\right)\right] \cdot \\
&\quad \exp\Big[-\frac{1}{2}\mathrm{tr}\big(T\big[Y^{\mathrm{T}}PY - Y^{\mathrm{T}}PXB - B^{\mathrm{T}}X^{\mathrm{T}}PY + B^{\mathrm{T}}X^{\mathrm{T}}PXB+ \\
&\qquad\qquad B^{\mathrm{T}}\Lambda_0 B - B^{\mathrm{T}}\Lambda_0 M_0 - M_0^{\mathrm{T}}\Lambda_0 B + M_0^{\mathrm{T}}\Lambda_0\mu_0\big]\big)\Big] \ .
\end{aligned} \tag{11}$$

Completing the square over B, we finally have

$$
p(Y, B, T) = \sqrt{\frac{|T|^n |P|^v}{(2\pi)^{nv}}} \sqrt{\frac{|T|^p |\Lambda_0|^v}{(2\pi)^{pv}}} \sqrt{\frac{|\Omega_0|^{\nu_0}}{2^{\nu_0 v}}} \frac{1}{\Gamma_v\left(\frac{\nu_0}{2}\right)} \cdot |T|^{(\nu_0 - v - 1)/2} \exp\left[-\frac{1}{2} \mathrm{tr}\left(\Omega_0 T\right)\right] \cdot
$$
$$
\exp\left[-\frac{1}{2} \mathrm{tr}\left(T\left[(B - M_n)^{\mathrm{T}} \Lambda_n (B - M_n) + (Y^{\mathrm{T}} P Y + M_0^{\mathrm{T}} \Lambda_0 M_0 - M_n^{\mathrm{T}} \Lambda_n M_n)\right]\right)\right] . \tag{12}
$$

with the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7)

$$
\begin{aligned}
M_n &= \Lambda_n^{-1}(X^{\mathrm{T}} P Y + \Lambda_0 M_0) \\
\Lambda_n &= X^{\mathrm{T}} P X + \Lambda_0 .
\end{aligned} \tag{13}
$$

Ergo, the joint likelihood is proportional to

$$
p(Y, B, T) \propto |T|^{p/2} \cdot \exp\left[-\frac{1}{2} \mathrm{tr}\left(T\left[(B - M_n)^{\mathrm{T}} \Lambda_n (B - M_n)\right]\right)\right] \cdot |T|^{(\nu_n - v - 1)/2} \cdot \exp\left[-\frac{1}{2} \mathrm{tr}\left(\Omega_n T\right)\right] \tag{14}
$$

with the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7)

$$
\begin{aligned}
\Omega_n &= \Omega_0 + Y^{\mathrm{T}} P Y + M_0^{\mathrm{T}} \Lambda_0 M_0 - M_n^{\mathrm{T}} \Lambda_n M_n \\
\nu_n &= \nu_0 + n .
\end{aligned} \tag{15}
$$

From the term in (14), we can isolate the posterior distribution over B given T:

$$
p(B|T, Y) = \mathcal{MN}(B; M_n, \Lambda_n^{-1}, T^{-1}) . \tag{16}
$$

From the remaining term, we can isolate the posterior distribution over T:

$$
p(T|Y) = \mathcal{W}(T; \Omega_n^{-1}, \nu_n) . \tag{17}
$$

Together, (16) and (17) constitute the joint ($\rightarrow$ Definition I/1.2.2) posterior distribution ($\rightarrow$ Definition I/5.1.7) of B and T.

2.2.3 Log model evidence

Theorem: Let

$$
Y = XB + E, \ E \sim \mathcal{MN}(0, V, \Sigma) \tag{1}
$$

be a general linear model ($\rightarrow$ Definition III/2.1.1) with measured $n \times v$ data matrix Y, known $n \times p$ design matrix X, known $n \times n$ covariance structure ($\rightarrow$ Definition II/5.1.1) V as well as unknown $p \times v$

regression coefficients B and unknown $v \times v$ noise covariance ($\rightarrow$ Definition II/5.1.1) Σ. Moreover, assume a normal-Wishart prior distribution ($\rightarrow$ Proof III/2.2.1) over the model parameters B and $T = \Sigma^{-1}$:

$$p(B, T) = \mathcal{MN}(B; M_0, \Lambda_0^{-1}, T^{-1}) \cdot \mathcal{W}(T; \Omega_0^{-1}, \nu_0) \ . \tag{2}$$

Then, the log model evidence ($\rightarrow$ Definition IV/3.1.1) for this model is

$$
\begin{aligned}
\log p(y|m) =& \frac{v}{2} \log|P| - \frac{nv}{2} \log(2\pi) + \frac{v}{2} \log|\Lambda_0| - \frac{v}{2} \log|\Lambda_n| + \\
& \frac{\nu_0}{2} \log\left|\frac{1}{2}\Omega_0\right| - \frac{\nu_n}{2} \log\left|\frac{1}{2}\Omega_n\right| + \log\Gamma_v\left(\frac{\nu_n}{2}\right) - \log\Gamma_v\left(\frac{\nu_0}{2}\right)
\end{aligned}
\tag{3}
$$

where the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$
\begin{aligned}
M_n &= \Lambda_n^{-1}(X^{\mathrm{T}}PY + \Lambda_0 M_0) \\
\Lambda_n &= X^{\mathrm{T}}PX + \Lambda_0 \\
\Omega_n &= \Omega_0 + Y^{\mathrm{T}}PY + M_0^{\mathrm{T}}\Lambda_0 M_0 - M_n^{\mathrm{T}}\Lambda_n M_n \\
\nu_n &= \nu_0 + n \ .
\end{aligned}
\tag{4}
$$

Proof: According to the law of marginal probability ($\rightarrow$ Definition I/1.2.3), the model evidence ($\rightarrow$ Definition I/5.1.9) for this model is:

$$p(Y|m) = \iint p(Y|B, T)\, p(B, T)\, \mathrm{d}B\, \mathrm{d}T \ . \tag{5}$$

According to the law of conditional probability ($\rightarrow$ Definition I/1.2.4), the integrand is equivalent to the joint likelihood ($\rightarrow$ Definition I/5.1.5):

$$p(Y|m) = \iint p(Y, B, T)\, \mathrm{d}B\, \mathrm{d}T \ . \tag{6}$$

Equation (1) implies the following likelihood function ($\rightarrow$ Definition I/5.1.2)

$$p(Y|B, \Sigma) = \mathcal{MN}(Y; XB, V, \Sigma) = \sqrt{\frac{1}{(2\pi)^{nv}|\Sigma|^n|V|^v}} \exp\left[-\frac{1}{2}\mathrm{tr}\left(\Sigma^{-1}(Y - XB)^{\mathrm{T}}V^{-1}(Y - XB)\right)\right] \tag{7}$$

which, for mathematical convenience, can also be parametrized as

$$p(Y|B, T) = \mathcal{MN}(Y; XB, P, T^{-1}) = \sqrt{\frac{|T|^n|P|^v}{(2\pi)^{nv}}} \exp\left[-\frac{1}{2}\mathrm{tr}\left(T(Y - XB)^{\mathrm{T}}P(Y - XB)\right)\right] \tag{8}$$

using the $v \times v$ precision matrix ($\rightarrow$ Definition I/1.7.9) $T = \Sigma^{-1}$ and the $n \times n$ precision matrix ($\rightarrow$ Definition I/1.7.9) $P = V^{-1}$.

When deriving the posterior distribution ($\rightarrow$ Proof III/2.2.2) $p(B, T|Y)$, the joint likelihood $p(Y, B, T)$ is obtained as

$$p(Y,B,T) = \sqrt{\frac{|T|^n|P|^v}{(2\pi)^{nv}}}\sqrt{\frac{|T|^p|\Lambda_0|^v}{(2\pi)^{pv}}}\sqrt{\frac{|\Omega_0|^{\nu_0}}{2^{\nu_0 v}}}\frac{1}{\Gamma_v\left(\frac{\nu_0}{2}\right)}\cdot|T|^{(\nu_0-v-1)/2}\exp\left[-\frac{1}{2}\mathrm{tr}\left(\Omega_0 T\right)\right]\cdot$$
$$\exp\left[-\frac{1}{2}\mathrm{tr}\left(T\left[(B-M_n)^{\mathrm{T}}\Lambda_n(B-M_n)+(Y^{\mathrm{T}}PY+M_0^{\mathrm{T}}\Lambda_0 M_0-M_n^{\mathrm{T}}\Lambda_n M_n)\right]\right)\right]\,. \tag{9}$$

Using the probability density function of the matrix-normal distribution ($\rightarrow$ Proof II/5.1.2), we can rewrite this as

$$p(Y,B,T) = \sqrt{\frac{|T|^n|P|^v}{(2\pi)^{nv}}}\sqrt{\frac{|T|^p|\Lambda_0|^v}{(2\pi)^{pv}}}\sqrt{\frac{(2\pi)^{pv}}{|T|^p|\Lambda_n|^v}}\sqrt{\frac{|\Omega_0|^{\nu_0}}{2^{\nu_0 v}}}\frac{1}{\Gamma_v\left(\frac{\nu_0}{2}\right)}\cdot|T|^{(\nu_0-v-1)/2}\exp\left[-\frac{1}{2}\mathrm{tr}\left(\Omega_0 T\right)\right]\cdot$$
$$\mathcal{MN}(B;M_n,\Lambda_n^{-1},T^{-1})\cdot\exp\left[-\frac{1}{2}\mathrm{tr}\left(T\left[Y^{\mathrm{T}}PY+M_0^{\mathrm{T}}\Lambda_0 M_0-M_n^{\mathrm{T}}\Lambda_n M_n\right]\right)\right]\,. \tag{10}$$

Now, B can be integrated out easily:

$$\int p(Y,B,T)\,\mathrm{d}B = \sqrt{\frac{|T|^n|P|^v}{(2\pi)^{nv}}}\sqrt{\frac{|\Lambda_0|^v}{|\Lambda_n|^v}}\sqrt{\frac{|\Omega_0|^{\nu_0}}{2^{\nu_0 v}}}\frac{1}{\Gamma_v\left(\frac{\nu_0}{2}\right)}\cdot|T|^{(\nu_0-v-1)/2}\cdot$$
$$\exp\left[-\frac{1}{2}\mathrm{tr}\left(T\left[\Omega_0+Y^{\mathrm{T}}PY+M_0^{\mathrm{T}}\Lambda_0 M_0-M_n^{\mathrm{T}}\Lambda_n M_n\right]\right)\right]\,. \tag{11}$$

Using the probability density function of the Wishart distribution ($\rightarrow$ Proof "wish-pdf"), we can rewrite this as

$$\int p(Y,B,T)\,\mathrm{d}B = \sqrt{\frac{|P|^v}{(2\pi)^{nv}}}\sqrt{\frac{|\Lambda_0|^v}{|\Lambda_n|^v}}\sqrt{\frac{|\Omega_0|^{\nu_0}}{2^{\nu_0 v}}}\sqrt{\frac{2^{\nu_n v}}{|\Omega_n|^{\nu_n}}}\frac{\Gamma_v\left(\frac{\nu_n}{2}\right)}{\Gamma_v\left(\frac{\nu_0}{2}\right)}\cdot\mathcal{W}(T;\Omega_n^{-1},\nu_n)\,. \tag{12}$$

Finally, T can also be integrated out:

$$\iint p(Y,B,T)\,\mathrm{d}B\,\mathrm{d}T = \sqrt{\frac{|P|^v}{(2\pi)^{nv}}}\sqrt{\frac{|\Lambda_0|^v}{|\Lambda_n|^v}}\sqrt{\frac{\left|\frac{1}{2}\Omega_0\right|^{\nu_0}}{\left|\frac{1}{2}\Omega_n\right|^{\nu_n}}}\frac{\Gamma_v\left(\frac{\nu_n}{2}\right)}{\Gamma_v\left(\frac{\nu_0}{2}\right)} = p(y|m)\,. \tag{13}$$

Thus, the log model evidence ($\rightarrow$ Definition IV/3.1.1) of this model is given by

$$\log p(y|m) = \frac{v}{2}\log|P| - \frac{nv}{2}\log(2\pi) + \frac{v}{2}\log|\Lambda_0| - \frac{v}{2}\log|\Lambda_n| +$$
$$\frac{\nu_0}{2}\log\left|\frac{1}{2}\Omega_0\right| - \frac{\nu_n}{2}\log\left|\frac{1}{2}\Omega_n\right| + \log\Gamma_v\left(\frac{\nu_n}{2}\right) - \log\Gamma_v\left(\frac{\nu_0}{2}\right)\,. \tag{14}$$

3   Poisson data

3.1   Poisson-distributed data

3.1.1   Definition

Definition: Poisson-distributed data are defined as a set of observed counts $y = \{y_1, \ldots, y_n\}$, independent and identically distributed according to a Poisson distribution ($\rightarrow$ Definition II/1.4.1) with rate λ:

$$y_i \sim \text{Poiss}(\lambda), \quad i = 1, \ldots, n \ . \tag{1}$$

Sources:
- Wikipedia (2020): "Poisson distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-22; URL: https://en.wikipedia.org/wiki/Poisson_distribution#Parameter_estimation.

Metadata: ID: D41 | shortcut: poiss-data | author: JoramSoch | date: 2020-03-22, 22:50.

3.1.2   Maximum likelihood estimation

Theorem: Let there be a Poisson-distributed data ($\rightarrow$ Definition III/3.1.1) set $y = \{y_1, \ldots, y_n\}$:

$$y_i \sim \text{Poiss}(\lambda), \quad i = 1, \ldots, n \ . \tag{1}$$

Then, the maximum likelihood estimate ($\rightarrow$ Definition I/4.1.3) for the rate parameter λ is given by

$$\hat{\lambda} = \bar{y} \tag{2}$$

where $\bar{y}$ is the sample mean ($\rightarrow$ Definition I/1.5.2)

$$\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i \ . \tag{3}$$

Proof: The likelihood function ($\rightarrow$ Definition I/5.1.2) for each observation is given by the probability mass function of the Poisson distribution ($\rightarrow$ Proof II/1.4.2)

$$p(y_i|\lambda) = \text{Poiss}(y_i; \lambda) = \frac{\lambda^{y_i} \cdot \exp(-\lambda)}{y_i!} \tag{4}$$

and because observations are independent ($\rightarrow$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$p(y|\lambda) = \prod_{i=1}^{n} p(y_i|\lambda) = \prod_{i=1}^{n} \frac{\lambda^{y_i} \cdot \exp(-\lambda)}{y_i!} \ . \tag{5}$$

Thus, the log-likelihood function ($\rightarrow$ Definition I/4.1.2) is

$$\text{LL}(\lambda) = \log p(y|\lambda) = \log \left[\prod_{i=1}^{n} \frac{\lambda^{y_i} \cdot \exp(-\lambda)}{y_i!} \right] \tag{6}$$

which can be developed into

$$
\begin{aligned}
\text{LL}(\lambda) &= \sum_{i=1}^{n} \log \left[\frac{\lambda^{y_i} \cdot \exp(-\lambda)}{y_i!} \right] \\
&= \sum_{i=1}^{n} [y_i \cdot \log(\lambda) - \lambda - \log(y_i!)] \\
&= -\sum_{i=1}^{n} \lambda + \sum_{i=1}^{n} y_i \cdot \log(\lambda) - \sum_{i=1}^{n} \log(y_i!) \\
&= -n\lambda + \log(\lambda) \sum_{i=1}^{n} y_i - \sum_{i=1}^{n} \log(y_i!)
\end{aligned}
\tag{7}
$$

The derivatives of the log-likelihood with respect to λ are

$$
\begin{aligned}
\frac{\text{dLL}(\lambda)}{\text{d}\lambda} &= \frac{1}{\lambda} \sum_{i=1}^{n} y_i - n \\
\frac{\text{d}^2\text{LL}(\lambda)}{\text{d}\lambda^2} &= -\frac{1}{\lambda^2} \sum_{i=1}^{n} y_i \;.
\end{aligned}
\tag{8}
$$

Setting the first derivative to zero, we obtain:

$$
\begin{aligned}
\frac{\text{dLL}(\hat{\lambda})}{\text{d}\lambda} &= 0 \\
0 &= \frac{1}{\hat{\lambda}} \sum_{i=1}^{n} y_i - n \\
\hat{\lambda} &= \frac{1}{n} \sum_{i=1}^{n} y_i = \bar{y} \;.
\end{aligned}
\tag{9}
$$

Plugging this value into the second derivative, we confirm:

$$
\begin{aligned}
\frac{\text{d}^2\text{LL}(\hat{\lambda})}{\text{d}\lambda^2} &= -\frac{1}{\bar{y}^2} \sum_{i=1}^{n} y_i \\
&= -\frac{n \cdot \bar{y}}{\bar{y}^2} \\
&= -\frac{n}{\bar{y}} < 0 \;.
\end{aligned}
\tag{10}
$$

This demonstrates that the estimate $\hat{\lambda} = \bar{y}$ maximizes the likelihood $p(y|\lambda)$.

3.1.3 Conjugate prior distribution

Theorem: Let there be a Poisson-distributed data ($\rightarrow$ Definition III/3.1.1) set $y = \{y_1, \ldots, y_n\}$:

$$y_i \sim \text{Poiss}(\lambda), \quad i = 1, \ldots, n \ . \tag{1}$$

Then, the conjugate prior ($\rightarrow$ Definition I/5.2.5) for the model parameter λ is a gamma distribution ($\rightarrow$ Definition II/3.4.1):

$$p(\lambda) = \text{Gam}(\lambda; a_0, b_0) \ . \tag{2}$$

Proof: With the probability mass function of the Poisson distribution ($\rightarrow$ Proof II/1.4.2), the likelihood function ($\rightarrow$ Definition I/5.1.2) for each observation implied by (1) is given by

$$p(y_i | \lambda) = \text{Poiss}(y_i; \lambda) = \frac{\lambda^{y_i} \cdot \exp\left[-\lambda\right]}{y_i!} \tag{3}$$

and because observations are independent ($\rightarrow$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$p(y | \lambda) = \prod_{i=1}^{n} p(y_i | \lambda) = \prod_{i=1}^{n} \frac{\lambda^{y_i} \cdot \exp\left[-\lambda\right]}{y_i!} \ . \tag{4}$$

Resolving the product in the likelihood function, we have

$$\begin{aligned}
p(y | \lambda) &= \prod_{i=1}^{n} \frac{1}{y_i!} \cdot \prod_{i=1}^{n} \lambda^{y_i} \cdot \prod_{i=1}^{n} \exp\left[-\lambda\right] \\
&= \prod_{i=1}^{n} \left(\frac{1}{y_i!}\right) \cdot \lambda^{n\bar{y}} \cdot \exp\left[-n\lambda\right]
\end{aligned} \tag{5}$$

where $\bar{y}$ is the mean ($\rightarrow$ Definition I/1.5.2) of y:

$$\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i \ . \tag{6}$$

In other words, the likelihood function is proportional to a power of λ times an exponential of λ:

$$p(y | \lambda) \propto \lambda^{n\bar{y}} \cdot \exp\left[-n\lambda\right] \ . \tag{7}$$

The same is true for a gamma distribution over λ

$$p(\lambda) = \text{Gam}(\lambda; a_0, b_0) \tag{8}$$

the probability density function of which ($\rightarrow$ Proof II/3.4.5)

$$p(\lambda) = \frac{b_0^{a_0}}{\Gamma(a_0)} \lambda^{a_0 - 1} \exp[-b_0 \lambda] \tag{9}$$

exhibits the same proportionality

$$p(\lambda) \propto \lambda^{a_0 - 1} \cdot \exp[-b_0 \lambda] \tag{10}$$

and is therefore conjugate relative to the likelihood.

3.1.4 Posterior distribution

Theorem: Let there be a Poisson-distributed data ($\rightarrow$ Definition III/3.1.1) set $y = \{y_1, \ldots, y_n\}$:

$$y_i \sim \mathrm{Poiss}(\lambda), \quad i = 1, \ldots, n \ . \tag{1}$$

Moreover, assume a gamma prior distribution ($\rightarrow$ Proof III/3.1.3) over the model parameter λ:

$$p(\lambda) = \mathrm{Gam}(\lambda; a_0, b_0) \ . \tag{2}$$

Then, the posterior distribution ($\rightarrow$ Definition I/5.1.7) is also a gamma distribution ($\rightarrow$ Definition II/3.4.1)

$$p(\lambda|y) = \mathrm{Gam}(\lambda; a_n, b_n) \tag{3}$$

and the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$\begin{aligned} a_n &= a_0 + n\bar{y} \\ b_n &= b_0 + n \ . \end{aligned} \tag{4}$$

Proof: With the probability mass function of the Poisson distribution ($\rightarrow$ Proof II/1.4.2), the likelihood function ($\rightarrow$ Definition I/5.1.2) for each observation implied by (1) is given by

$$p(y_i|\lambda) = \mathrm{Poiss}(y_i; \lambda) = \frac{\lambda^{y_i} \cdot \exp[-\lambda]}{y_i!} \tag{5}$$

and because observations are independent ($\rightarrow$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$p(y|\lambda) = \prod_{i=1}^{n} p(y_i|\lambda) = \prod_{i=1}^{n} \frac{\lambda^{y_i} \cdot \exp[-\lambda]}{y_i!} \ . \tag{6}$$

Combining the likelihood function (6) with the prior distribution (2), the joint likelihood ($\rightarrow$ Definition I/5.1.5) of the model is given by

$$\begin{aligned} p(y, \lambda) &= p(y|\lambda) \, p(\lambda) \\ &= \prod_{i=1}^{n} \frac{\lambda^{y_i} \cdot \exp[-\lambda]}{y_i!} \cdot \frac{b_0^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda] \ . \end{aligned} \tag{7}$$

Resolving the product in the joint likelihood, we have

$$ p(y, \lambda) = \prod_{i=1}^{n} \frac{1}{y_i!} \prod_{i=1}^{n} \lambda^{y_i} \prod_{i=1}^{n} \exp\left[-\lambda\right] \cdot \frac{b_0{}^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda] $$

$$ = \prod_{i=1}^{n} \left(\frac{1}{y_i!}\right) \lambda^{n\bar{y}} \exp\left[-n\lambda\right] \cdot \frac{b_0{}^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda] \tag{8} $$

$$ = \prod_{i=1}^{n} \left(\frac{1}{y_i!}\right) \cdot \frac{b_0{}^{a_0}}{\Gamma(a_0)} \cdot \lambda^{a_0+n\bar{y}-1} \cdot \exp\left[-(b_0+n\lambda)\right] $$

where $\bar{y}$ is the mean ($\rightarrow$ Definition I/1.5.2) of y:

$$ \bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i \; . \tag{9} $$

Note that the posterior distribution is proportional to the joint likelihood ($\rightarrow$ Proof I/5.1.8):

$$ p(\lambda|y) \propto p(y, \lambda) \; . \tag{10} $$

Setting $a_n = a_0 + n\bar{y}$ and $b_n = b_0 + n$, the posterior distribution is therefore proportional to

$$ p(\lambda|y) \propto \lambda^{a_n-1} \cdot \exp\left[-b_n\lambda\right] \tag{11} $$

which, when normalized to one, results in the probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5):

$$ p(\lambda|y) = \frac{b_n{}^{a_n}}{\Gamma(a_0)} \lambda^{a_n-1} \exp\left[-b_n\lambda\right] = \mathrm{Gam}(\lambda; a_n, b_n) \; . \tag{12} $$

Sources:
- Gelman A, Carlin JB, Stern HS, Dunson DB, Vehtari A, Rubin DB (2014): "Other standard single-parameter models"; in: *Bayesian Data Analysis*, 3rd edition, ch. 2.6, p. 45, eq. 2.15; URL: http://www.stat.columbia.edu/~gelman/book/.

3.1.5 Log model evidence

Theorem: Let there be a Poisson-distributed data ($\rightarrow$ Definition III/3.1.1) set $y = \{y_1, \dots, y_n\}$:

$$ y_i \sim \mathrm{Poiss}(\lambda), \quad i = 1, \dots, n \; . \tag{1} $$

Moreover, assume a gamma prior distribution ($\rightarrow$ Proof III/3.1.3) over the model parameter λ:

$$ p(\lambda) = \mathrm{Gam}(\lambda; a_0, b_0) \; . \tag{2} $$

Then, the log model evidence ($\rightarrow$ Definition IV/3.1.1) for this model is

$$ \log p(y|m) = -\sum_{i=1}^{n} \log y_i! + \log \Gamma(a_n) - \log \Gamma(a_0) + a_0 \log b_0 - a_n \log b_n \; . \tag{3} $$

and the posterior hyperparameters ($\to$ Definition I/5.1.7) are given by

$$
\begin{aligned}
a_n &= a_0 + n\bar{y} \\
b_n &= b_0 + n \ .
\end{aligned}
\tag{4}
$$

Proof: With the probability mass function of the Poisson distribution ($\to$ Proof II/1.4.2), the likelihood function ($\to$ Definition I/5.1.2) for each observation implied by (1) is given by

$$
p(y_i|\lambda) = \text{Poiss}(y_i; \lambda) = \frac{\lambda^{y_i} \cdot \exp\left[-\lambda\right]}{y_i!}
\tag{5}
$$

and because observations are independent ($\to$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$
p(y|\lambda) = \prod_{i=1}^{n} p(y_i|\lambda) = \prod_{i=1}^{n} \frac{\lambda^{y_i} \cdot \exp\left[-\lambda\right]}{y_i!} \ .
\tag{6}
$$

Combining the likelihood function (6) with the prior distribution (2), the joint likelihood ($\to$ Definition I/5.1.5) of the model is given by

$$
\begin{aligned}
p(y, \lambda) &= p(y|\lambda)\, p(\lambda) \\
&= \prod_{i=1}^{n} \frac{\lambda^{y_i} \cdot \exp\left[-\lambda\right]}{y_i!} \cdot \frac{b_0{}^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda] \ .
\end{aligned}
\tag{7}
$$

Resolving the product in the joint likelihood, we have

$$
\begin{aligned}
p(y, \lambda) &= \prod_{i=1}^{n} \frac{1}{y_i!} \prod_{i=1}^{n} \lambda^{y_i} \prod_{i=1}^{n} \exp\left[-\lambda\right] \cdot \frac{b_0{}^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda] \\
&= \prod_{i=1}^{n} \left(\frac{1}{y_i!}\right) \lambda^{n\bar{y}} \exp\left[-n\lambda\right] \cdot \frac{b_0{}^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda] \\
&= \prod_{i=1}^{n} \left(\frac{1}{y_i!}\right) \cdot \frac{b_0{}^{a_0}}{\Gamma(a_0)} \cdot \lambda^{a_0+n\bar{y}-1} \cdot \exp\left[-(b_0 + n\lambda)\right]
\end{aligned}
\tag{8}
$$

where $\bar{y}$ is the mean ($\to$ Definition I/1.5.2) of y:

$$
\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i \ .
\tag{9}
$$

Note that the model evidence is the marginal density of the joint likelihood ($\to$ Definition I/5.1.9):

$$
p(y) = \int p(y, \lambda)\, \mathrm{d}\lambda \ .
\tag{10}
$$

Setting $a_n = a_0 + n\bar{y}$ and $b_n = b_0 + n$, the joint likelihood can also be written as

$$
p(y, \lambda) = \prod_{i=1}^{n} \left(\frac{1}{y_i!}\right) \frac{b_0{}^{a_0}}{\Gamma(a_0)} \frac{\Gamma(a_n)}{b_n{}^{a_n}} \cdot \frac{b_n{}^{a_n}}{\Gamma(a_n)} \lambda^{a_n-1} \exp\left[-b_n\lambda\right] \ .
\tag{11}
$$

Using the probability density function of the gamma distribution ($\rightarrow$ Proof II/3.4.5), λ can now be integrated out easily

$$
\begin{aligned}
\mathrm{p}(y) &= \int \prod_{i=1}^{n} \left(\frac{1}{y_i!} \right) \frac{b_0{}^{a_0}}{\Gamma(a_0)} \frac{\Gamma(a_n)}{b_n{}^{a_n}} \cdot \frac{b_n{}^{a_n}}{\Gamma(a_n)} \lambda^{a_n-1} \exp\left[-b_n\lambda\right] \mathrm{d}\lambda \\
&= \prod_{i=1}^{n} \left(\frac{1}{y_i!} \right) \frac{\Gamma(a_n)}{\Gamma(a_0)} \frac{b_0{}^{a_0}}{b_n{}^{a_n}} \int \mathrm{Gam}(\lambda; a_n, b_n) \, \mathrm{d}\lambda \\
&= \prod_{i=1}^{n} \left(\frac{1}{y_i!} \right) \frac{\Gamma(a_n)}{\Gamma(a_0)} \frac{b_0{}^{a_0}}{b_n{}^{a_n}} \,,
\end{aligned}
\tag{12}
$$

such that the log model evidence ($\rightarrow$ Definition IV/3.1.1) is shown to be

$$
\log p(y|m) = -\sum_{i=1}^{n} \log y_i! + \log \Gamma(a_n) - \log \Gamma(a_0) + a_0 \log b_0 - a_n \log b_n \,.
\tag{13}
$$

3.2   Poisson distribution with exposure values

3.2.1   Definition

Definition: A Poisson distribution with exposure values is defined as a set of observed counts $y = \{y_1, \ldots, y_n\}$, independently distributed according to a Poisson distribution ($\rightarrow$ Definition II/1.4.1) with common rate λ and a set of concurrent exposures $x = \{x_1, \ldots, x_n\}$:

$$
y_i \sim \mathrm{Poiss}(\lambda x_i), \quad i = 1, \ldots, n \,.
\tag{1}
$$

Sources:
- Gelman A, Carlin JB, Stern HS, Dunson DB, Vehtari A, Rubin DB (2014): "Other standard single-parameter models"; in: *Bayesian Data Analysis*, 3rd edition, ch. 2.6, p. 45, eq. 2.14; URL: http://www.stat.columbia.edu/~gelman/book/.

Metadata: ID: D42 | shortcut: poissexp | author: JoramSoch | date: 2020-03-22, 22:57.

3.2.2   Maximum likelihood estimation

Theorem: Consider data $y = \{y_1, \ldots, y_n\}$ following a Poisson distribution with exposure values ($\rightarrow$ Definition III/3.2.1):

$$
y_i \sim \mathrm{Poiss}(\lambda x_i), \quad i = 1, \ldots, n \,.
\tag{1}
$$

Then, the maximum likelihood estimate ($\rightarrow$ Definition I/4.1.3) for the rate parameter λ is given by

$$\hat{\lambda} = \frac{\bar{y}}{\bar{x}} \tag{2}$$

where $\bar{y}$ and $\bar{x}$ are the sample means ($\rightarrow$ Definition "mean-sample")

$$\begin{aligned}
\bar{y} &= \frac{1}{n} \sum_{i=1}^{n} y_i \\
\bar{x} &= \frac{1}{n} \sum_{i=1}^{n} x_i \; .
\end{aligned} \tag{3}$$

Proof: With the probability mass function of the Poisson distribution ($\rightarrow$ Proof II/1.4.2), the likelihood function ($\rightarrow$ Definition I/5.1.2) for each observation implied by (1) is given by

$$p(y_i|\lambda) = \mathrm{Poiss}(y_i; \lambda x_i) = \frac{(\lambda x_i)^{y_i} \cdot \exp[-\lambda x_i]}{y_i!} \tag{4}$$

and because observations are independent ($\rightarrow$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$p(y|\lambda) = \prod_{i=1}^{n} p(y_i|\lambda) = \prod_{i=1}^{n} \frac{(\lambda x_i)^{y_i} \cdot \exp[-\lambda x_i]}{y_i!} \; . \tag{5}$$

Thus, the log-likelihood function ($\rightarrow$ Definition I/4.1.2) is

$$\mathrm{LL}(\lambda) = \log p(y|\lambda) = \log \left[\prod_{i=1}^{n} \frac{(\lambda x_i)^{y_i} \cdot \exp[-\lambda x_i]}{y_i!} \right] \tag{6}$$

which can be developed into

$$\begin{aligned}
\mathrm{LL}(\lambda) &= \sum_{i=1}^{n} \log \left[\frac{(\lambda x_i)^{y_i} \cdot \exp[-\lambda x_i]}{y_i!} \right] \\
&= \sum_{i=1}^{n} \left[y_i \cdot \log(\lambda x_i) - \lambda x_i - \log(y_i!) \right] \\
&= -\sum_{i=1}^{n} \lambda x_i + \sum_{i=1}^{n} y_i \cdot \left[\log(\lambda) + \log(x_i) \right] - \sum_{i=1}^{n} \log(y_i!) \\
&= -\lambda \sum_{i=1}^{n} x_i + \log(\lambda) \sum_{i=1}^{n} y_i + \sum_{i=1}^{n} y_i \log(x_i) - \sum_{i=1}^{n} \log(y_i!) \\
&= -n\bar{x}\lambda + n\bar{y} \log(\lambda) + \sum_{i=1}^{n} y_i \log(x_i) - \sum_{i=1}^{n} \log(y_i!)
\end{aligned} \tag{7}$$

where $\bar{x}$ and $\bar{y}$ are the sample means from equation (3).

The derivatives of the log-likelihood with respect to λ are

$$\frac{\mathrm{dLL}(\lambda)}{\mathrm{d}\lambda} = -n\bar{x} + \frac{n\bar{y}}{\lambda}$$
$$\frac{\mathrm{d^2LL}(\lambda)}{\mathrm{d}\lambda^2} = -\frac{n\bar{y}}{\lambda^2} \ . \tag{8}$$

Setting the first derivative to zero, we obtain:

$$\frac{\mathrm{dLL}(\hat{\lambda})}{\mathrm{d}\lambda} = 0$$
$$0 = -n\bar{x} + \frac{n\bar{y}}{\hat{\lambda}} \tag{9}$$
$$\hat{\lambda} = \frac{n\bar{y}}{n\bar{x}} = \frac{\bar{y}}{\bar{x}} \ .$$

Plugging this value into the second derivative, we confirm:

$$\frac{\mathrm{d^2LL}(\hat{\lambda})}{\mathrm{d}\lambda^2} = -\frac{n\bar{y}}{\hat{\lambda}^2}$$
$$= -\frac{n \cdot \bar{y}}{(\bar{y}/\bar{x})^2} \tag{10}$$
$$= -\frac{n \cdot \bar{x}^2}{\bar{y}} < 0 \ .$$

This demonstrates that the estimate $\hat{\lambda} = \bar{y}/\bar{x}$ maximizes the likelihood $p(y|\lambda)$.

3.2.3 Conjugate prior distribution

Theorem: Consider data $y = \{y_1, \ldots, y_n\}$ following a Poisson distribution with exposure values ($\rightarrow$ Definition III/3.2.1):

$$y_i \sim \mathrm{Poiss}(\lambda x_i), \quad i = 1, \ldots, n \ . \tag{1}$$

Then, the conjugate prior ($\rightarrow$ Definition I/5.2.5) for the model parameter λ is a gamma distribution ($\rightarrow$ Definition II/3.4.1):

$$p(\lambda) = \mathrm{Gam}(\lambda; a_0, b_0) \ . \tag{2}$$

Proof: With the probability mass function of the Poisson distribution ($\rightarrow$ Proof II/1.4.2), the likelihood function ($\rightarrow$ Definition I/5.1.2) for each observation implied by (1) is given by

$$p(y_i|\lambda) = \mathrm{Poiss}(y_i; \lambda x_i) = \frac{(\lambda x_i)^{y_i} \cdot \exp\left[-\lambda x_i\right]}{y_i!} \tag{3}$$

and because observations are independent ($\rightarrow$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$p(y|\lambda) = \prod_{i=1}^{n} p(y_i|\lambda) = \prod_{i=1}^{n} \frac{(\lambda x_i)^{y_i} \cdot \exp\left[-\lambda x_i\right]}{y_i!} \ . \tag{4}$$

Resolving the product in the likelihood function, we have

$$
\begin{aligned}
p(y|\lambda) &= \prod_{i=1}^{n} \frac{x_i^{y_i}}{y_i!} \cdot \prod_{i=1}^{n} \lambda^{y_i} \cdot \prod_{i=1}^{n} \exp\left[-\lambda x_i\right] \\
&= \prod_{i=1}^{n} \left(\frac{x_i^{y_i}}{y_i!}\right) \cdot \lambda^{\sum_{i=1}^{n} y_i} \cdot \exp\left[-\lambda \sum_{i=1}^{n} x_i\right] \\
&= \prod_{i=1}^{n} \left(\frac{x_i^{y_i}}{y_i!}\right) \cdot \lambda^{n\bar{y}} \cdot \exp\left[-n\bar{x}\lambda\right]
\end{aligned}
\tag{5}
$$

where $\bar{y}$ and $\bar{x}$ are the means ($\rightarrow$ Definition I/1.5.2) of y and x respectively:

$$
\begin{aligned}
\bar{y} &= \frac{1}{n} \sum_{i=1}^{n} y_i \\
\bar{x} &= \frac{1}{n} \sum_{i=1}^{n} x_i \ .
\end{aligned}
\tag{6}
$$

In other words, the likelihood function is proportional to a power of λ times an exponential of λ:

$$p(y|\lambda) \propto \lambda^{n\bar{y}} \cdot \exp\left[-n\bar{x}\lambda\right] \ . \tag{7}$$

The same is true for a gamma distribution over λ

$$p(\lambda) = \mathrm{Gam}(\lambda; a_0, b_0) \tag{8}$$

the probability density function of which ($\rightarrow$ Proof II/3.4.5)

$$p(\lambda) = \frac{b_0^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda] \tag{9}$$

exhibits the same proportionality

$$p(\lambda) \propto \lambda^{a_0-1} \cdot \exp[-b_0\lambda] \tag{10}$$

and is therefore conjugate relative to the likelihood.

3.2.4 Posterior distribution

Theorem: Consider data $y = \{y_1, \ldots, y_n\}$ following a Poisson distribution with exposure values ($\rightarrow$ Definition III/3.2.1):

$$y_i \sim \mathrm{Poiss}(\lambda x_i), \quad i = 1, \ldots, n \; . \tag{1}$$

Moreover, assume a gamma prior distribution ($\rightarrow$ Proof III/3.2.3) over the model parameter λ:

$$p(\lambda) = \mathrm{Gam}(\lambda; a_0, b_0) \; . \tag{2}$$

Then, the posterior distribution ($\rightarrow$ Definition I/5.1.7) is also a gamma distribution ($\rightarrow$ Definition II/3.4.1)

$$p(\lambda|y) = \mathrm{Gam}(\lambda; a_n, b_n) \tag{3}$$

and the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$\begin{aligned} a_n &= a_0 + n\bar{y} \\ b_n &= b_0 + n\bar{x} \; . \end{aligned} \tag{4}$$

Proof: With the probability mass function of the Poisson distribution ($\rightarrow$ Proof II/1.4.2), the likelihood function ($\rightarrow$ Definition I/5.1.2) for each observation implied by (1) is given by

$$p(y_i|\lambda) = \mathrm{Poiss}(y_i; \lambda x_i) = \frac{(\lambda x_i)^{y_i} \cdot \exp\left[-\lambda x_i\right]}{y_i!} \tag{5}$$

and because observations are independent ($\rightarrow$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$p(y|\lambda) = \prod_{i=1}^{n} p(y_i|\lambda) = \prod_{i=1}^{n} \frac{(\lambda x_i)^{y_i} \cdot \exp\left[-\lambda x_i\right]}{y_i!} \; . \tag{6}$$

Combining the likelihood function (6) with the prior distribution (2), the joint likelihood ($\rightarrow$ Definition I/5.1.5) of the model is given by

$$\begin{aligned} p(y, \lambda) &= p(y|\lambda)\, p(\lambda) \\ &= \prod_{i=1}^{n} \frac{(\lambda x_i)^{y_i} \cdot \exp\left[-\lambda x_i\right]}{y_i!} \cdot \frac{b_0{}^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda] \; . \end{aligned} \tag{7}$$

Resolving the product in the joint likelihood, we have

$$
\begin{aligned}
p(y, \lambda) &= \prod_{i=1}^{n} \frac{x_i^{\,y_i}}{y_i!} \prod_{i=1}^{n} \lambda^{y_i} \prod_{i=1}^{n} \exp\left[-\lambda x_i\right] \cdot \frac{b_0^{\,a_0}}{\Gamma(a_0)} \lambda^{a_0 - 1} \exp[-b_0 \lambda] \\
&= \prod_{i=1}^{n} \left(\frac{x_i^{\,y_i}}{y_i!} \right) \lambda^{\sum_{i=1}^{n} y_i} \exp\left[-\lambda \sum_{i=1}^{n} x_i\right] \cdot \frac{b_0^{\,a_0}}{\Gamma(a_0)} \lambda^{a_0 - 1} \exp[-b_0 \lambda] \\
&= \prod_{i=1}^{n} \left(\frac{x_i^{\,y_i}}{y_i!} \right) \lambda^{n\bar{y}} \exp\left[-n\bar{x}\lambda\right] \cdot \frac{b_0^{\,a_0}}{\Gamma(a_0)} \lambda^{a_0 - 1} \exp[-b_0 \lambda] \\
&= \prod_{i=1}^{n} \left(\frac{x_i^{\,y_i}}{y_i!} \right) \cdot \frac{b_0^{\,a_0}}{\Gamma(a_0)} \cdot \lambda^{a_0 + n\bar{y} - 1} \cdot \exp\left[-(b_0 + n\bar{x})\lambda\right]
\end{aligned}
\tag{8}
$$

where $\bar{y}$ and $\bar{x}$ are the means ($\to$ Definition I/1.5.2) of y and x respectively:

$$
\begin{aligned}
\bar{y} &= \frac{1}{n} \sum_{i=1}^{n} y_i \\
\bar{x} &= \frac{1}{n} \sum_{i=1}^{n} x_i \; .
\end{aligned}
\tag{9}
$$

Note that the posterior distribution is proportional to the joint likelihood ($\to$ Proof I/5.1.8):

$$
p(\lambda|y) \propto p(y, \lambda) \; .
\tag{10}
$$

Setting $a_n = a_0 + n\bar{y}$ and $b_n = b_0 + n\bar{x}$, the posterior distribution is therefore proportional to

$$
p(\lambda|y) \propto \lambda^{a_n - 1} \cdot \exp\left[-b_n \lambda\right]
\tag{11}
$$

which, when normalized to one, results in the probability density function of the gamma distribution ($\to$ Proof II/3.4.5):

$$
p(\lambda|y) = \frac{b_n^{\,a_n}}{\Gamma(a_0)} \lambda^{a_n - 1} \exp\left[-b_n \lambda\right] = \mathrm{Gam}(\lambda; a_n, b_n) \; .
\tag{12}
$$

3.2.5 Log model evidence

Theorem: Consider data $y = \{y_1, \ldots, y_n\}$ following a Poisson distribution with exposure values ($\to$ Definition III/3.2.1):

$$
y_i \sim \mathrm{Poiss}(\lambda x_i), \quad i = 1, \ldots, n \; .
\tag{1}
$$

Moreover, assume a gamma prior distribution ($\to$ Proof III/3.2.3) over the model parameter λ:

$$p(\lambda) = \mathrm{Gam}(\lambda; a_0, b_0) \ . \tag{2}$$

Then, the log model evidence ($\to$ Definition IV/3.1.1) for this model is

$$\log p(y|m) = \sum_{i=1}^{n} y_i \log(x_i) - \sum_{i=1}^{n} \log y_i! + $$
$$\log \Gamma(a_n) - \log \Gamma(a_0) + a_0 \log b_0 - a_n \log b_n \ . \tag{3}$$

where the posterior hyperparameters ($\to$ Definition I/5.1.7) are given by

$$a_n = a_0 + n\bar{y}$$
$$a_n = a_0 + n\bar{x} \ . \tag{4}$$

Proof: With the probability mass function of the Poisson distribution ($\to$ Proof II/1.4.2), the likelihood function ($\to$ Definition I/5.1.2) for each observation implied by (1) is given by

$$p(y_i|\lambda) = \mathrm{Poiss}(y_i; \lambda x_i) = \frac{(\lambda x_i)^{y_i} \cdot \exp\left[-\lambda x_i\right]}{y_i!} \tag{5}$$

and because observations are independent ($\to$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$p(y|\lambda) = \prod_{i=1}^{n} p(y_i|\lambda) = \prod_{i=1}^{n} \frac{(\lambda x_i)^{y_i} \cdot \exp\left[-\lambda x_i\right]}{y_i!} \ . \tag{6}$$

Combining the likelihood function (6) with the prior distribution (2), the joint likelihood ($\to$ Definition I/5.1.5) of the model is given by

$$p(y, \lambda) = p(y|\lambda)\, p(\lambda)$$
$$= \prod_{i=1}^{n} \frac{(\lambda x_i)^{y_i} \cdot \exp\left[-\lambda x_i\right]}{y_i!} \cdot \frac{b_0^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda] \ . \tag{7}$$

Resolving the product in the joint likelihood, we have

$$p(y, \lambda) = \prod_{i=1}^{n} \frac{x_i^{y_i}}{y_i!} \prod_{i=1}^{n} \lambda^{y_i} \prod_{i=1}^{n} \exp\left[-\lambda x_i\right] \cdot \frac{b_0^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda]$$
$$= \prod_{i=1}^{n} \left(\frac{x_i^{y_i}}{y_i!}\right) \lambda^{\sum_{i=1}^{n} y_i} \exp\left[-\lambda \sum_{i=1}^{n} x_i\right] \cdot \frac{b_0^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda]$$
$$= \prod_{i=1}^{n} \left(\frac{x_i^{y_i}}{y_i!}\right) \lambda^{n\bar{y}} \exp\left[-n\bar{x}\lambda\right] \cdot \frac{b_0^{a_0}}{\Gamma(a_0)} \lambda^{a_0-1} \exp[-b_0\lambda] \tag{8}$$
$$= \prod_{i=1}^{n} \left(\frac{x_i^{y_i}}{y_i!}\right) \frac{b_0^{a_0}}{\Gamma(a_0)} \cdot \lambda^{a_0+n\bar{y}-1} \cdot \exp\left[-(b_0 + n\bar{x})\lambda\right]$$

where $\bar{y}$ and $\bar{x}$ are the means ($\to$ Definition I/1.5.2) of y and x respectively:

$$
\begin{aligned}
\bar{y} &= \frac{1}{n} \sum_{i=1}^{n} y_i \\
\bar{x} &= \frac{1}{n} \sum_{i=1}^{n} x_i \; .
\end{aligned}
\tag{9}
$$

Note that the model evidence is the marginal density of the joint likelihood ($\to$ Definition I/5.1.9):

$$
p(y) = \int p(y, \lambda) \, \mathrm{d}\lambda \; .
\tag{10}
$$

Setting $a_n = a_0 + n\bar{y}$ and $b_n = b_0 + n\bar{x}$, the joint likelihood can also be written as

$$
p(y, \lambda) = \prod_{i=1}^{n} \left(\frac{x_i^{y_i}}{y_i!} \right) \frac{b_0^{a_0}}{\Gamma(a_0)} \frac{\Gamma(a_n)}{b_n^{a_n}} \cdot \frac{b_n^{a_n}}{\Gamma(a_n)} \lambda^{a_n - 1} \exp\left[-b_n \lambda \right] \; .
\tag{11}
$$

Using the probability density function of the gamma distribution ($\to$ Proof II/3.4.5), λ can now be integrated out easily

$$
\begin{aligned}
\mathrm{p}(y) &= \int \prod_{i=1}^{n} \left(\frac{x_i^{y_i}}{y_i!} \right) \frac{b_0^{a_0}}{\Gamma(a_0)} \frac{\Gamma(a_n)}{b_n^{a_n}} \cdot \frac{b_n^{a_n}}{\Gamma(a_n)} \lambda^{a_n - 1} \exp\left[-b_n \lambda \right] \, \mathrm{d}\lambda \\
&= \prod_{i=1}^{n} \left(\frac{x_i^{y_i}}{y_i!} \right) \frac{\Gamma(a_n)}{\Gamma(a_0)} \frac{b_0^{a_0}}{b_n^{a_n}} \int \mathrm{Gam}(\lambda; a_n, b_n) \, \mathrm{d}\lambda \\
&= \prod_{i=1}^{n} \left(\frac{x_i^{y_i}}{y_i!} \right) \frac{\Gamma(a_n)}{\Gamma(a_0)} \frac{b_0^{a_0}}{b_n^{a_n}} \; ,
\end{aligned}
\tag{12}
$$

such that the log model evidence ($\to$ Definition IV/3.1.1) is shown to be

$$
\begin{aligned}
\log p(y|m) = \sum_{i=1}^{n} y_i \log(x_i) - \sum_{i=1}^{n} \log y_i! + \\
\log \Gamma(a_n) - \log \Gamma(a_0) + a_0 \log b_0 - a_n \log b_n \; .
\end{aligned}
\tag{13}
$$

4 Probability data

4.1 Beta-distributed data

4.1.1 Definition

Definition: Beta-distributed data are defined as a set of proportions $y = \{y_1, \ldots, y_n\}$ with $y_i \in [0, 1]$, $i = 1, \ldots, n$, independent and identically distributed according to a Beta distribution ($\rightarrow$ Definition II/3.8.1) with shapes α and β:

$$y_i \sim \mathrm{Bet}(\alpha, \beta), \quad i = 1, \ldots, n \, . \tag{1}$$

Sources:

- original work

Metadata: ID: D77 | shortcut: beta-data | author: JoramSoch | date: 2020-06-28, 21:16.

4.1.2 Method of moments

Theorem: Let $y = \{y_1, \ldots, y_n\}$ be a set of observed counts independent and identically distributed ($\rightarrow$ Definition "iid") according to a beta distribution ($\rightarrow$ Definition II/3.8.1) with shapes α and β:

$$y_i \sim \mathrm{Bet}(\alpha, \beta), \quad i = 1, \ldots, n \, . \tag{1}$$

Then, the method-of-moments estimates ($\rightarrow$ Definition I/4.1.5) for the shape parameters α and β are given by

$$
\begin{aligned}
\hat{\alpha} &= \bar{y} \left(\frac{\bar{y}(1 - \bar{y})}{\bar{v}} - 1 \right) \\
\hat{\beta} &= (1 - \bar{y}) \left(\frac{\bar{y}(1 - \bar{y})}{\bar{v}} - 1 \right)
\end{aligned}
\tag{2}
$$

where $\bar{y}$ is the sample mean ($\rightarrow$ Definition I/1.5.2) and $\bar{v}$ is the unbiased sample variance ($\rightarrow$ Definition I/1.6.2):

$$
\begin{aligned}
\bar{y} &= \frac{1}{n} \sum_{i=1}^{n} y_i \\
\bar{v} &= \frac{1}{n-1} \sum_{i=1}^{n} (y_i - \bar{y})^2 \, .
\end{aligned}
\tag{3}
$$

Proof: Mean ($\rightarrow$ Proof II/3.8.5) and variance ($\rightarrow$ Proof II/3.8.6) of the beta distribution ($\rightarrow$ Definition II/3.8.1) in terms of the parameters α and β are given by

$$
\begin{aligned}
\mathrm{E}(X) &= \frac{\alpha}{\alpha + \beta} \\
\mathrm{Var}(X) &= \frac{\alpha\beta}{(\alpha + \beta)^2(\alpha + \beta + 1)} \, .
\end{aligned}
\tag{4}
$$

Thus, matching the moments ($\to$ Definition I/4.1.5) requires us to solve the following equation system for α and β:

$$\bar{y} = \frac{\alpha}{\alpha + \beta}$$

$$\bar{v} = \frac{\alpha\beta}{(\alpha + \beta)^2(\alpha + \beta + 1)} \ . \tag{5}$$

From the first equation, we can deduce:

$$\bar{y}(\alpha + \beta) = \alpha$$
$$\alpha\bar{y} + \beta\bar{y} = \alpha$$
$$\beta\bar{y} = \alpha - \alpha\bar{y}$$
$$\beta = \frac{\alpha}{\bar{y}} - \alpha \tag{6}$$
$$\beta = \alpha\left(\frac{1}{\bar{y}} - 1\right) \ .$$

If we define $q = 1/\bar{y} - 1$ and plug (6) into the second equation, we have:

$$\bar{v} = \frac{\alpha \cdot \alpha q}{(\alpha + \alpha q)^2(\alpha + \alpha q + 1)}$$
$$= \frac{\alpha^2 q}{(\alpha(1+q))^2(\alpha(1+q) + 1)}$$
$$= \frac{q}{(1+q)^2(\alpha(1+q) + 1)} \tag{7}$$
$$= \frac{q}{\alpha(1+q)^3 + (1+q)^2}$$
$$q = \bar{v}\left[\alpha(1+q)^3 + (1+q)^2\right] \ .$$

Noting that $1 + q = 1/\bar{y}$ and $q = (1 - \bar{y})/\bar{y}$, one obtains for α:

$$\frac{1 - \bar{y}}{\bar{y}} = \bar{v}\left[\frac{\alpha}{\bar{y}^3} + \frac{1}{\bar{y}^2}\right]$$
$$\frac{1 - \bar{y}}{\bar{y}\,\bar{v}} = \frac{\alpha}{\bar{y}^3} + \frac{1}{\bar{y}^2}$$
$$\frac{\bar{y}^3(1 - \bar{y})}{\bar{y}\,\bar{v}} = \alpha + \bar{y} \tag{8}$$
$$\alpha = \frac{\bar{y}^2(1 - \bar{y})}{\bar{v}} - \bar{y}$$
$$= \bar{y}\left(\frac{\bar{y}(1 - \bar{y})}{\bar{v}} - 1\right) \ .$$

Plugging this into equation (6), one obtains for β:

$$\beta = \bar{y} \left(\frac{\bar{y}(1 - \bar{y})}{\bar{v}} - 1 \right) \cdot \left(\frac{1 - \bar{y}}{\bar{y}} \right)$$

$$= (1 - \bar{y}) \left(\frac{\bar{y}(1 - \bar{y})}{\bar{v}} - 1 \right) . \tag{9}$$

Together, (8) and (9) constitute the method-of-moment estimates of α and β.

4.2 Dirichlet-distributed data

4.2.1 Definition

Definition: Dirichlet-distributed data are defined as a set of vectors of proportions $y = \{y_1, \ldots, y_n\}$ where

$$\begin{aligned} y_i &= [y_{i1}, \ldots, y_{ik}], \\ y_{ij} &\in [0, 1] \quad \text{and} \\ \sum_{j=1}^{k} y_{ij} &= 1 \end{aligned} \tag{1}$$

for all $i = 1, \ldots, n$ (and $j = 1, \ldots, k$) and each y_i is independent and identically distributed according to a Dirichlet distribution ($\rightarrow$ Definition II/4.4.1) with concentration parameters $\alpha = [\alpha_1, \ldots, \alpha_k]$:

$$y_i \sim \mathrm{Dir}(\alpha), \quad i = 1, \ldots, n . \tag{2}$$

Sources:
- original work

Metadata: ID: D104 | shortcut: dir-data | author: JoramSoch | date: 2020-10-22, 05:06.

4.2.2 Maximum likelihood estimation

Theorem: Let there be a Dirichlet-distributed data ($\rightarrow$ Definition III/4.2.1) set $y = \{y_1, \ldots, y_n\}$:

$$y_i \sim \mathrm{Dir}(\alpha), \quad i = 1, \ldots, n . \tag{1}$$

Then, the maximum likelihood estimate ($\rightarrow$ Definition I/4.1.3) for the concentration parameters α can be obtained by iteratively computing

$$\alpha_j^{(\mathrm{new})} = \psi^{-1} \left[\psi \left(\sum_{j=1}^{k} \alpha_j^{(\mathrm{old})} \right) + \log \bar{y}_j \right] \tag{2}$$

where $\psi(x)$ is the digamma function and $\log \bar{y}_j$ is given by:

$$\log \bar{y}_j = \frac{1}{n} \sum_{i=1}^{n} \log y_{ij} \ . \tag{3}$$

Proof: The likelihood function ($\rightarrow$ Definition I/5.1.2) for each observation is given by the probability density function of the Dirichlet distribution ($\rightarrow$ Proof II/4.4.2)

$$p(y_i|\alpha) = \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_j\right)}{\prod_{j=1}^{k} \Gamma(\alpha_j)} \prod_{j=1}^{k} y_{ij}^{\alpha_j - 1} \tag{4}$$

and because observations are independent ($\rightarrow$ Definition I/1.2.6), the likelihood function for all observations is the product of the individual ones:

$$p(y|\alpha) = \prod_{i=1}^{n} p(y_i|\alpha) = \prod_{i=1}^{n} \left[\frac{\Gamma\left(\sum_{j=1}^{k} \alpha_j\right)}{\prod_{j=1}^{k} \Gamma(\alpha_j)} \prod_{j=1}^{k} y_{ij}^{\alpha_j - 1} \right] \ . \tag{5}$$

Thus, the log-likelihood function ($\rightarrow$ Definition I/4.1.2) is

$$\mathrm{LL}(\alpha) = \log p(y|\alpha) = \log \prod_{i=1}^{n} \left[\frac{\Gamma\left(\sum_{j=1}^{k} \alpha_j\right)}{\prod_{j=1}^{k} \Gamma(\alpha_j)} \prod_{j=1}^{k} y_{ij}^{\alpha_j - 1} \right] \tag{6}$$

which can be developed into

$$\begin{aligned}
\mathrm{LL}(\alpha) &= \sum_{i=1}^{n} \log \Gamma\left(\sum_{j=1}^{k} \alpha_j\right) - \sum_{i=1}^{n} \sum_{j=1}^{k} \log \Gamma(\alpha_j) + \sum_{i=1}^{n} \sum_{j=1}^{k} (\alpha_j - 1) \log y_{ij} \\
&= n \log \Gamma\left(\sum_{j=1}^{k} \alpha_j\right) - n \sum_{j=1}^{k} \log \Gamma(\alpha_j) + n \sum_{j=1}^{k} (\alpha_j - 1) \frac{1}{n} \sum_{i=1}^{n} \log y_{ij} \\
&= n \log \Gamma\left(\sum_{j=1}^{k} \alpha_j\right) - n \sum_{j=1}^{k} \log \Gamma(\alpha_j) + n \sum_{j=1}^{k} (\alpha_j - 1) \log \bar{y}_j
\end{aligned} \tag{7}$$

where we have specified

$$\log \bar{y}_j = \frac{1}{n} \sum_{i=1}^{n} \log y_{ij} \ . \tag{8}$$

The derivative of the log-likelihood with respect to a particular parameter α_j is

$$\begin{aligned}
\frac{\mathrm{dLL}(\alpha)}{\mathrm{d}\alpha_j} &= \frac{\mathrm{d}}{\mathrm{d}\alpha_j} \left[n \log \Gamma\left(\sum_{j=1}^{k} \alpha_j\right) - n \sum_{j=1}^{k} \log \Gamma(\alpha_j) + n \sum_{j=1}^{k} (\alpha_j - 1) \log \bar{y}_j \right] \\
&= \frac{\mathrm{d}}{\mathrm{d}\alpha_j} \left[n \log \Gamma\left(\sum_{j=1}^{k} \alpha_j\right) \right] - \frac{\mathrm{d}}{\mathrm{d}\alpha_j} \left[n \log \Gamma(\alpha_j) \right] + \frac{\mathrm{d}}{\mathrm{d}\alpha_j} \left[n(\alpha_j - 1) \log \bar{y}_j \right] \\
&= n\psi\left(\sum_{j=1}^{k} \alpha_j\right) - n\psi(\alpha_j) + n \log \bar{y}_j
\end{aligned} \tag{9}$$

where we have used the digamma function

$$\psi(x) = \frac{\mathrm{d} \log \Gamma(x)}{\mathrm{d}x} \; . \tag{10}$$

Setting this derivative to zero, we obtain:

$$\frac{\mathrm{dLL}(\alpha)}{\mathrm{d}\alpha_j} = 0$$

$$0 = n\psi\left(\sum_{j=1}^{k} \alpha_j\right) - n\psi(\alpha_j) + n \log \bar{y}_j$$

$$0 = \psi\left(\sum_{j=1}^{k} \alpha_j\right) - \psi(\alpha_j) + \log \bar{y}_j \tag{11}$$

$$\psi(\alpha_j) = \psi\left(\sum_{j=1}^{k} \alpha_j\right) + \log \bar{y}_j$$

$$\alpha_j = \psi^{-1}\left[\psi\left(\sum_{j=1}^{k} \alpha_j\right) + \log \bar{y}_j\right] \; .$$

In the following, we will use a fixed-point iteration to maximize $\mathrm{LL}(\alpha)$. Given an initial guess for α, we construct a lower bound on the likelihood function (7) which is tight at α. The maximum of this bound is computed and it becomes the new guess. Because the Dirichlet distribution ($\rightarrow$ Definition II/4.4.1) belongs to the exponential family ($\rightarrow$ Definition "dist-expfam"), the log-likelihood function is convex in α ánd the maximum is the only stationary point, such that the procedure is guaranteed to converge to the maximum.

In our case, we use a bound on the gamma function

$$\Gamma(x) \geq \Gamma(\hat{x}) \cdot \exp\left[(x - \hat{x})\,\psi(\hat{x})\right]$$
$$\log \Gamma(x) \geq \log \Gamma(\hat{x}) + (x - \hat{x})\,\psi(\hat{x}) \tag{12}$$

and apply it to $\Gamma\left(\sum_{j=1}^{k} \alpha_j\right)$ in (7) to yield

$$\frac{1}{n}\mathrm{LL}(\alpha) = \log \Gamma\left(\sum_{j=1}^{k} \alpha_j\right) - \sum_{j=1}^{k} \log \Gamma(\alpha_j) + \sum_{j=1}^{k} (\alpha_j - 1) \log \bar{y}_j$$

$$\frac{1}{n}\mathrm{LL}(\alpha) \geq \log \Gamma\left(\sum_{j=1}^{k} \hat{\alpha}_j\right) + \left(\sum_{j=1}^{k} \alpha_j - \sum_{j=1}^{k} \hat{\alpha}_j\right)\psi\left(\sum_{j=1}^{k} \hat{\alpha}_j\right) - \sum_{j=1}^{k} \log \Gamma(\alpha_j) + \sum_{j=1}^{k} (\alpha_j - 1) \log \bar{y}_j$$

$$\frac{1}{n}\mathrm{LL}(\alpha) \geq \left(\sum_{j=1}^{k} \alpha_j\right)\psi\left(\sum_{j=1}^{k} \hat{\alpha}_j\right) - \sum_{j=1}^{k} \log \Gamma(\alpha_j) + \sum_{j=1}^{k} (\alpha_j - 1) \log \bar{y}_j + \mathrm{const.}$$

$$\tag{13}$$

which leads to the following fixed-point iteration using (11):

$$\alpha_j^{(\text{new})} = \psi^{-1} \left[\psi \left(\sum_{j=1}^{k} \alpha_j^{(\text{old})} \right) + \log \bar{y}_j \right] . \tag{14}$$

5   Categorical data

5.1   Binomial observations

5.1.1   Definition

Definition: An ordered pair (n, y) with $n \in \mathbb{N}$ and $y \in \mathbb{N}_0$, where y is the number of successes in n trials, consititutes a set of binomial observations.

Sources:

- original work

Metadata: ID: D78 | shortcut: bin-data | author: JoramSoch | date: 2020-07-07, 07:04.

5.1.2   Conjugate prior distribution

Theorem: Let y be the number of successes resulting from n independent trials with unknown success probability p, such that y follows a binomial distribution ($\rightarrow$ Definition II/1.3.1):

$$y \sim \mathrm{Bin}(n, p) \;. \tag{1}$$

Then, the conjugate prior ($\rightarrow$ Definition I/5.2.5) for the model parameter p is a beta distribution ($\rightarrow$ Definition II/3.8.1):

$$\mathrm{p}(p) = \mathrm{Bet}(p; \alpha_0, \beta_0) \;. \tag{2}$$

Proof: With the probability mass function of the binomial distribution ($\rightarrow$ Proof II/1.3.2), the likelihood function ($\rightarrow$ Definition I/5.1.2) implied by (1) is given by

$$\mathrm{p}(y|p) = \binom{n}{y} p^y \, (1-p)^{n-y} \;. \tag{3}$$

In other words, the likelihood function is proportional to a power of p times a power of $(1-p)$:

$$\mathrm{p}(y|p) \propto p^y \, (1-p)^{n-y} \;. \tag{4}$$

The same is true for a beta distribution over p

$$\mathrm{p}(p) = \mathrm{Bet}(p; \alpha_0, \beta_0) \tag{5}$$

the probability density function of which ($\rightarrow$ Proof II/3.8.2)

$$\mathrm{p}(p) = \frac{1}{B(\alpha_0, \beta_0)} \, p^{\alpha_0 - 1} \, (1-p)^{\beta_0 - 1} \tag{6}$$

exhibits the same proportionality

$$\mathrm{p}(p) \propto p^{\alpha_0 - 1} \, (1-p)^{\beta_0 - 1} \tag{7}$$

and is therefore conjugate relative to the likelihood.

5.1.3 Posterior distribution

Theorem: Let y be the number of successes resulting from n independent trials with unknown success probability p, such that y follows a binomial distribution ($\to$ Definition II/1.3.1):

$$y \sim \mathrm{Bin}(n, p) \,. \tag{1}$$

Moreover, assume a beta prior distribution ($\to$ Proof III/5.1.2) over the model parameter p:

$$\mathrm{p}(p) = \mathrm{Bet}(p; \alpha_0, \beta_0) \,. \tag{2}$$

Then, the posterior distribution ($\to$ Definition I/5.1.7) is also a beta distribution ($\to$ Definition II/3.8.1)

$$\mathrm{p}(p|y) = \mathrm{Bet}(p; \alpha_n, \beta_n) \,. \tag{3}$$

and the posterior hyperparameters ($\to$ Definition I/5.1.7) are given by

$$\begin{aligned} \alpha_n &= \alpha_0 + y \\ \beta_n &= \beta_0 + (n - y) \,. \end{aligned} \tag{4}$$

Proof: With the probability mass function of the binomial distribution ($\to$ Proof II/1.3.2), the likelihood function ($\to$ Definition I/5.1.2) implied by (1) is given by

$$\mathrm{p}(y|p) = \binom{n}{y} p^y \, (1 - p)^{n-y} \,. \tag{5}$$

Combining the likelihood function (5) with the prior distribution (2), the joint likelihood ($\to$ Definition I/5.1.5) of the model is given by

$$\begin{aligned} \mathrm{p}(y, p) &= \mathrm{p}(y|p) \, \mathrm{p}(p) \\ &= \binom{n}{y} p^y \, (1 - p)^{n-y} \cdot frac1B(\alpha_0, \beta_0) \, p^{\alpha_0 - 1} \, (1 - p)^{\beta_0 - 1} \\ &= \frac{1}{B(\alpha_0, \beta_0)} \binom{n}{y} p^{\alpha_0 + y - 1} \, (1 - p)^{\beta_0 + (n - y) - 1} \,. \end{aligned} \tag{6}$$

Note that the posterior distribution is proportional to the joint likelihood ($\to$ Proof I/5.1.8):

$$\mathrm{p}(p|y) \propto \mathrm{p}(y, p) \,. \tag{7}$$

Setting $\alpha_n = \alpha_0 + y$ and $\beta_n = \beta_0 + (n - y)$, the posterior distribution is therefore proportional to

$$\mathrm{p}(p|y) \propto p^{\alpha_n - 1} \, (1 - p)^{\beta_n - 1} \tag{8}$$

which, when normalized to one, results in the probability density function of the beta distribution
($\rightarrow$ Proof II/3.8.2):

$$p(p|y) = \frac{1}{B(\alpha_n, \beta_n)} \, p^{\alpha_n - 1} \, (1 - p)^{\beta_n - 1} = \text{Bet}(p; \alpha_n, \beta_n) \ . \tag{9}$$

Sources:

5.1.4 Log model evidence

Theorem: Let y be the number of successes resulting from n independent trials with unknown
success probability p, such that y follows a binomial distribution ($\rightarrow$ Definition II/1.3.1):

$$y \sim \text{Bin}(n, p) \ . \tag{1}$$

Moreover, assume a beta prior distribution ($\rightarrow$ Proof III/5.1.2) over the model parameter p:

$$p(p) = \text{Bet}(p; \alpha_0, \beta_0) \ . \tag{2}$$

Then, the log model evidence ($\rightarrow$ Definition IV/3.1.1) for this model is

$$
\begin{aligned}
\log p(y|m) = {} & \log \Gamma(n + 1) - \log \Gamma(k + 1) - \log \Gamma(n - k + 1) \\
& + \log B(\alpha_n, \beta_n) - \log B(\alpha_0, \beta_0) \ .
\end{aligned}
\tag{3}
$$

where the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$
\begin{aligned}
\alpha_n &= \alpha_0 + y \\
\beta_n &= \beta_0 + (n - y) \ .
\end{aligned}
\tag{4}
$$

Proof: With the probability mass function of the binomial distribution ($\rightarrow$ Proof II/1.3.2), the
likelihood function ($\rightarrow$ Definition I/5.1.2) implied by (1) is given by

$$p(y|p) = \binom{n}{y} \, p^y \, (1 - p)^{n-y} \ . \tag{5}$$

Combining the likelihood function (5) with the prior distribution (2), the joint likelihood ($\rightarrow$ Definition I/5.1.5) of the model is given by

$$
\begin{aligned}
p(y, p) &= p(y|p) \, p(p) \\
&= \binom{n}{y} \, p^y \, (1 - p)^{n-y} \cdot frac1B(\alpha_0, \beta_0) \, p^{\alpha_0 - 1} \, (1 - p)^{\beta_0 - 1} \\
&= \binom{n}{y} \, \frac{1}{B(\alpha_0, \beta_0)} \, p^{\alpha_0 + y - 1} \, (1 - p)^{\beta_0 + (n - y) - 1} \ .
\end{aligned}
\tag{6}
$$

Note that the model evidence is the marginal density of the joint likelihood ($\rightarrow$ Definition I/5.1.9):

$$\mathrm{p}(y) = \int \mathrm{p}(y, p)\, \mathrm{d}p \ . \tag{7}$$

Setting $\alpha_n = \alpha_0 + y$ and $\beta_n = \beta_0 + (n - y)$, the joint likelihood can also be written as

$$\mathrm{p}(y, p) = \binom{n}{y} \frac{1}{B(\alpha_0, \beta_0)} \frac{B(\alpha_n, \beta_n)}{1} \frac{1}{B(\alpha_n, \beta_n)} p^{\alpha_n - 1} (1 - p)^{\beta_n - 1} \ . \tag{8}$$

Using the probability density function of the beta distribution ($\rightarrow$ Proof II/3.8.2), p can now be integrated out easily

$$
\begin{aligned}
\mathrm{p}(y) &= \int \binom{n}{y} \frac{1}{B(\alpha_0, \beta_0)} \frac{B(\alpha_n, \beta_n)}{1} \frac{1}{B(\alpha_n, \beta_n)} p^{\alpha_n - 1} (1 - p)^{\beta_n - 1} \, \mathrm{d}p \\
&= \binom{n}{y} \frac{B(\alpha_n, \beta_n)}{B(\alpha_0, \beta_0)} \int \mathrm{Bet}(p; \alpha_n, \beta_n) \, \mathrm{d}p \\
&= \binom{n}{y} \frac{B(\alpha_n, \beta_n)}{B(\alpha_0, \beta_0)} \ ,
\end{aligned} \tag{9}
$$

such that the log model evidence ($\rightarrow$ Definition IV/3.1.1) (LME) is shown to be

$$\log \mathrm{p}(y|m) = \log \binom{n}{y} + \log B(\alpha_n, \beta_n) - \log B(\alpha_0, \beta_0) \ . \tag{10}$$

With the definition of the binomial coefficient

$$\binom{n}{k} = \frac{n!}{k!\,(n - k)!} \tag{11}$$

and the definition of the gamma function

$$\Gamma(n) = (n - 1)! \ , \tag{12}$$

the LME finally becomes

$$
\begin{aligned}
\log \mathrm{p}(y|m) = {}& \log \Gamma(n + 1) - \log \Gamma(k + 1) - \log \Gamma(n - k + 1) \\
& + \log B(\alpha_n, \beta_n) - \log B(\alpha_0, \beta_0) \ .
\end{aligned} \tag{13}
$$

5.2   Multinomial observations

5.2.1   Definition

Definition: An ordered pair (n, y) with $n \in \mathbb{N}$ and $y = [y_1, \ldots, y_k] \in \mathbb{N}_0^{1 \times k}$, where y_i is the number of observations for the i-th out of k categories obtained in n trials, $i = 1, \ldots, k$, consititutes a set of multinomial observations.

Sources:
- original work

Metadata: ID: D79 | shortcut: mult-data | author: JoramSoch | date: 2020-07-07, 07:12.

5.2.2   Conjugate prior distribution

Theorem: Let $y = [y_1, \ldots, y_k]$ be the number of observations in k categories resulting from n independent trials with unknown category probabilities $p = [p_1, \ldots, p_k]$, such that y follows a multinomial distribution ($\rightarrow$ Definition II/2.2.1):

$$y \sim \mathrm{Mult}(n, p) \; . \tag{1}$$

Then, the conjugate prior ($\rightarrow$ Definition I/5.2.5) for the model parameter p is a Dirichlet distribution ($\rightarrow$ Definition II/4.4.1):

$$\mathrm{p}(p) = \mathrm{Dir}(p; \alpha_0) \; . \tag{2}$$

Proof: With the probability mass function of the multinomial distribution ($\rightarrow$ Proof II/2.2.2), the likelihood function ($\rightarrow$ Definition I/5.1.2) implied by (1) is given by

$$\mathrm{p}(y|p) = \binom{n}{y_1, \ldots, y_k} \prod_{j=1}^{k} p_j^{\,y_j} \; . \tag{3}$$

In other words, the likelihood function is proportional to a product of powers of the entries of the vector p:

$$\mathrm{p}(y|p) \propto \prod_{j=1}^{k} p_j^{\,y_j} \; . \tag{4}$$

The same is true for a Dirichlet distribution over p

$$\mathrm{p}(p) = \mathrm{Dir}(p; \alpha_0) \tag{5}$$

the probability density function of which ($\rightarrow$ Proof II/4.4.2)

$$\mathrm{p}(p) = \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{0j})} \prod_{j=1}^{k} p_j^{\,\alpha_{0j}-1} \tag{6}$$

exhibits the same proportionality

$$\mathrm{p}(p) \propto \prod_{j=1}^{k} p_j{}^{\alpha_{0j}-1} \tag{7}$$

and is therefore conjugate relative to the likelihood.

Sources:
- Wikipedia (2020): "Dirichlet distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-11; URL: https://en.wikipedia.org/wiki/Dirichlet_distribution#Conjugate_to_categorical/multinomi

5.2.3 Posterior distribution

Theorem: Let $y = [y_1, \ldots, y_k]$ be the number of observations in k categories resulting from n independent trials with unknown category probabilities $p = [p_1, \ldots, p_k]$, such that y follows a multinomial distribution ($\to$ Definition II/2.2.1):

$$y \sim \mathrm{Mult}(n, p) . \tag{1}$$

Moreover, assume a Dirichlet prior distribution ($\to$ Proof III/5.2.2) over the model parameter p:

$$\mathrm{p}(p) = \mathrm{Dir}(p; \alpha_0) . \tag{2}$$

Then, the posterior distribution ($\to$ Definition I/5.1.7) is also a Dirichlet distribution ($\to$ Definition II/4.4.1)

$$\mathrm{p}(p|y) = \mathrm{Dir}(p; \alpha_n) . \tag{3}$$

and the posterior hyperparameters ($\to$ Definition I/5.1.7) are given by

$$\alpha_{nj} = \alpha_{0j} + y_j, \ j = 1, \ldots, k . \tag{4}$$

Proof: With the probability mass function of the multinomial distribution ($\to$ Proof II/2.2.2), the likelihood function ($\to$ Definition I/5.1.2) implied by (1) is given by

$$\mathrm{p}(y|p) = \binom{n}{y_1, \ldots, y_k} \prod_{j=1}^{k} p_j{}^{y_j} . \tag{5}$$

Combining the likelihood function (5) with the prior distribution (2), the joint likelihood ($\to$ Definition I/5.1.5) of the model is given by

$$
\begin{aligned}
\mathrm{p}(y, p) &= \mathrm{p}(y|p)\,\mathrm{p}(p) \\
&= \binom{n}{y_1, \ldots, y_k} \prod_{j=1}^{k} p_j{}^{y_j} \cdot \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{0j})} \prod_{j=1}^{k} p_j{}^{\alpha_{0j}-1} \\
&= \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{0j})} \binom{n}{y_1, \ldots, y_k} \prod_{j=1}^{k} p_j{}^{\alpha_{0j}+y_j-1} .
\end{aligned}
\tag{6}
$$

Note that the posterior distribution is proportional to the joint likelihood ($\rightarrow$ Proof I/5.1.8):

$$\mathrm{p}(p|y) \propto \mathrm{p}(y, p) \ . \tag{7}$$

Setting $\alpha_{nj} = \alpha_{0j} + y_j$, the posterior distribution is therefore proportional to

$$\mathrm{p}(p|y) \propto \prod_{j=1}^{k} p_j^{\,\alpha_{nj}-1} \tag{8}$$

which, when normalized to one, results in the probability density function of the Dirichlet distribution ($\rightarrow$ Proof II/4.4.2):

$$\mathrm{p}(p|y) = \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{nj}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{nj})} \prod_{j=1}^{k} p_j^{\,\alpha_{nj}-1} = \mathrm{Dir}(p; \alpha_n) \ . \tag{9}$$

Sources:
- Wikipedia (2020): "Dirichlet distribution"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-03-11; URL: https://en.wikipedia.org/wiki/Dirichlet_distribution#Conjugate_to_categorical/multinomi

5.2.4   Log model evidence

Theorem: Let $y = [y_1, \ldots, y_k]$ be the number of observations in k categories resulting from n independent trials with unknown category probabilities $p = [p_1, \ldots, p_k]$, such that y follows a multinomial distribution ($\rightarrow$ Definition II/2.2.1):

$$y \sim \mathrm{Mult}(n, p) \ . \tag{1}$$

Moreover, assume a Dirichlet prior distribution ($\rightarrow$ Proof III/5.2.2) over the model parameter p:

$$\mathrm{p}(p) = \mathrm{Dir}(p; \alpha_0) \ . \tag{2}$$

Then, the log model evidence ($\rightarrow$ Definition IV/3.1.1) for this model is

$$
\begin{aligned}
\log \mathrm{p}(y|m) = \log \Gamma(n+1) &- \sum_{j=1}^{k} \log \Gamma(k_j + 1) \\
&+ \log \Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right) - \log \Gamma\left(\sum_{j=1}^{k} \alpha_{nj}\right) \\
&+ \sum_{j=1}^{k} \log \Gamma(\alpha_{nj}) - \sum_{j=1}^{k} \log \Gamma(\alpha_{0j}) \ .
\end{aligned}
\tag{3}
$$

and the posterior hyperparameters ($\rightarrow$ Definition I/5.1.7) are given by

$$\alpha_{nj} = \alpha_{0j} + y_j, \ j = 1, \ldots, k \ . \tag{4}$$

Proof: With the probability mass function of the multinomial distribution ($\rightarrow$ Proof II/2.2.2), the likelihood function ($\rightarrow$ Definition I/5.1.2) implied by (1) is given by

$$\mathrm{p}(y|p) = \binom{n}{y_1, \ldots, y_k} \prod_{j=1}^{k} p_j{}^{y_j} . \tag{5}$$

Combining the likelihood function (5) with the prior distribution (2), the joint likelihood ($\rightarrow$ Definition I/5.1.5) of the model is given by

$$
\begin{aligned}
\mathrm{p}(y, p) &= \mathrm{p}(y|p)\,\mathrm{p}(p) \\
&= \binom{n}{y_1, \ldots, y_k} \prod_{j=1}^{k} p_j{}^{y_j} \cdot \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{0j})} \prod_{j=1}^{k} p_j{}^{\alpha_{0j}-1} \\
&= \binom{n}{y_1, \ldots, y_k} \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{0j})} \prod_{j=1}^{k} p_j{}^{\alpha_{0j}+y_j-1} .
\end{aligned}
\tag{6}
$$

Note that the model evidence is the marginal density of the joint likelihood:

$$\mathrm{p}(y) = \int \mathrm{p}(y, p)\,\mathrm{d}p . \tag{7}$$

Setting $\alpha_{nj} = \alpha_{0j} + y_j$, the joint likelihood can also be written as

$$\mathrm{p}(y, p) = \binom{n}{y_1, \ldots, y_k} \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{0j})} \frac{\prod_{j=1}^{k} \Gamma(\alpha_{nj})}{\Gamma\left(\sum_{j=1}^{k} \alpha_{nj}\right)} \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{nj}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{nj})} \prod_{j=1}^{k} p_j{}^{\alpha_{nj}-1} . \tag{8}$$

Using the probability density function of the Dirichlet distribution ($\rightarrow$ Proof II/4.4.2), p can now be integrated out easily

$$
\begin{aligned}
\mathrm{p}(y) &= \int \binom{n}{y_1, \ldots, y_k} \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{0j})} \frac{\prod_{j=1}^{k} \Gamma(\alpha_{nj})}{\Gamma\left(\sum_{j=1}^{k} \alpha_{nj}\right)} \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{nj}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{nj})} \prod_{j=1}^{k} p_j{}^{\alpha_{nj}-1}\,\mathrm{d}p \\
&= \binom{n}{y_1, \ldots, y_k} \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right)}{\prod_{j=1}^{k} \Gamma(\alpha_{0j})} \frac{\prod_{j=1}^{k} \Gamma(\alpha_{nj})}{\Gamma\left(\sum_{j=1}^{k} \alpha_{nj}\right)} \int \mathrm{Dir}(p; \alpha_n)\,\mathrm{d}p \\
&= \binom{n}{y_1, \ldots, y_k} \frac{\Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right)}{\Gamma\left(\sum_{j=1}^{k} \alpha_{nj}\right)} \frac{\prod_{j=1}^{k} \Gamma(\alpha_{nj})}{\prod_{j=1}^{k} \Gamma(\alpha_{0j})} ,
\end{aligned}
\tag{9}
$$

such that the log model evidence ($\rightarrow$ Definition IV/3.1.1) (LME) is shown to be

$$
\begin{aligned}
\log \mathrm{p}(y|m) = {}& \log \binom{n}{y_1, \ldots, y_k} + \log \Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right) - \log \Gamma\left(\sum_{j=1}^{k} \alpha_{nj}\right) \\
& + \sum_{j=1}^{k} \log \Gamma(\alpha_{nj}) - \sum_{j=1}^{k} \log \Gamma(\alpha_{0j}) .
\end{aligned}
\tag{10}
$$

With the definition of the multinomial coefficient

$$\binom{n}{k_1, \ldots, k_m} = \frac{n!}{k_1! \cdot \ldots \cdot k_m!} \tag{11}$$

and the definition of the gamma function

$$\Gamma(n) = (n-1)! \,, \tag{12}$$

the LME finally becomes

$$
\begin{aligned}
\log \mathrm{p}(y|m) = {} & \log \Gamma(n+1) - \sum_{j=1}^{k} \log \Gamma(k_j + 1) \\
& + \log \Gamma\left(\sum_{j=1}^{k} \alpha_{0j}\right) - \log \Gamma\left(\sum_{j=1}^{k} \alpha_{nj}\right) \\
& + \sum_{j=1}^{k} \log \Gamma(\alpha_{nj}) - \sum_{j=1}^{k} \log \Gamma(\alpha_{0j}) \,.
\end{aligned}
\tag{13}
$$

5.3   Logistic regression

5.3.1   Definition

Definition: A logistic regression model is given by a set of binary observations $y_i \in \{0, 1\}, i = 1, \ldots, n$, a set of predictors $x_j \in \mathbb{R}^n, j = 1, \ldots, p$, a base b and the assumption that the log-odds are a linear combination of the predictors:

$$l_i = x_i \beta + \varepsilon_i, \; i = 1, \ldots, n \tag{1}$$

where l_i are the log-odds that $y_i = 1$

$$l_i = \log_b \frac{\Pr(y_i = 1)}{\Pr(y_i = 0)} \tag{2}$$

and x_i is the i-th row of the $n \times p$ matrix

$$X = [x_1, \ldots, x_p] \,. \tag{3}$$

Within this model,
- y are called "categorical observations" or "dependent variable";
- X is called "design matrix" or "set of independent variables";
- β are called "regression coefficients" or "weights";
- ε_i is called "noise" or "error term";
- n is the number of observations;

- p is the number of predictors.

- Wikipedia (2020): "Logistic regression"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-06-28; URL: https://en.wikipedia.org/wiki/Logistic_regression#Logistic_model.

Metadata: ID: D76 | shortcut: logreg | author: JoramSoch | date: 2020-06-28, 20:51.

5.3.2 Probability and log-odds

Theorem: Assume a logistic regression model ($\to$ Definition III/5.3.1)

$$l_i = x_i\beta + \varepsilon_i, \; i = 1, \dots, n \tag{1}$$

where x_i are the predictors corresponding to the i-th observation y_i and l_i are the log-odds that $y_i = 1$.
Then, the log-odds in favor of $y_i = 1$ against $y_i = 0$ can also be expressed as

$$l_i = \log_b \frac{p(x_i|y_i = 1)\, p(y_i = 1)}{p(x_i|y_i = 0)\, p(y_i = 0)} \tag{2}$$

where $p(x_i|y_i)$ is a likelihood function ($\to$ Definition I/5.1.2) consistent with (1), $p(y_i)$ are prior probabilities ($\to$ Definition I/5.1.3) for $y_i = 1$ and $y_i = 0$ and where b is the base used to form the log-odds l_i.

Proof: Using Bayes' theorem ($\to$ Proof I/5.3.1) and the law of marginal probability ($\to$ Definition I/1.2.3), the posterior probabilities ($\to$ Definition I/5.1.7) for $y_i = 1$ and $y_i = 0$ are given by

$$
\begin{aligned}
p(y_i = 1|x_i) &= \frac{p(x_i|y_i = 1)\, p(y_i = 1)}{p(x_i|y_i = 1)\, p(y_i = 1) + p(x_i|y_i = 0)\, p(y_i = 0)} \\
p(y_i = 0|x_i) &= \frac{p(x_i|y_i = 0)\, p(y_i = 0)}{p(x_i|y_i = 1)\, p(y_i = 1) + p(x_i|y_i = 0)\, p(y_i = 0)} \; .
\end{aligned}
\tag{3}
$$

Calculating the log-odds from the posterior probabilties, we have

$$
\begin{aligned}
l_i &= \log_b \frac{p(y_i = 1|x_i)}{p(y_i = 0|x_i)} \\
&= \log_b \frac{p(x_i|y_i = 1)\, p(y_i = 1)}{p(x_i|y_i = 0)\, p(y_i = 0)} \; .
\end{aligned}
\tag{4}
$$

5.3.3 Log-odds and probability

Theorem: Assume a logistic regression model ($\to$ Definition III/5.3.1)

$$l_i = x_i\beta + \varepsilon_i, \; i = 1, \ldots, n \tag{1}$$

where x_i are the predictors corresponding to the i-th observation y_i and l_i are the log-odds that $y_i = 1$.

Then, the probability that $y_i = 1$ is given by

$$\Pr(y_i = 1) = \frac{1}{1 + b^{-(x_i\beta + \varepsilon_i)}} \tag{2}$$

where b is the base used to form the log-odds l_i.

Proof: Let us denote $\Pr(y_i = 1)$ as p_i. Then, the log-odds are

$$l_i = \log_b \frac{p_i}{1 - p_i} \tag{3}$$

and using (1), we have

$$
\begin{aligned}
\log_b \frac{p_i}{1 - p_i} &= x_i\beta + \varepsilon_i \\
\frac{p_i}{1 - p_i} &= b^{x_i\beta + \varepsilon_i} \\
p_i &= \left(b^{x_i\beta + \varepsilon_i}\right)(1 - p_i) \\
p_i\left(1 + b^{x_i\beta + \varepsilon_i}\right) &= b^{x_i\beta + \varepsilon_i} \\
p_i &= \frac{b^{x_i\beta + \varepsilon_i}}{1 + b^{x_i\beta + \varepsilon_i}} \\
p_i &= \frac{b^{x_i\beta + \varepsilon_i}}{b^{x_i\beta + \varepsilon_i}\left(1 + b^{-(x_i\beta + \varepsilon_i)}\right)} \\
p_i &= \frac{1}{1 + b^{-(x_i\beta + \varepsilon_i)}}
\end{aligned}
\tag{4}
$$

which proves the identity given by (2).

Chapter IV

Model Selection

1   Goodness-of-fit measures

1.1   Residual variance

1.1.1   Definition

Definition: Let there be a linear regression model ($\rightarrow$ Definition III/1.3.1)

$$y = X\beta + \varepsilon, \ \varepsilon \sim \mathcal{N}(0, \sigma^2 V) \tag{1}$$

with measured data y, known design matrix X and covariance structure V as well as unknown regression coefficients β and noise variance σ^2.

Then, an estimate of the noise variance σ^2 is called the "residual variance" $\hat{\sigma}^2$, e.g. obtained via maximum likelihood estimation ($\rightarrow$ Definition I/4.1.3).

Sources:
- original work

Metadata: ID: D20 | shortcut: resvar | author: JoramSoch | date: 2020-02-25, 11:21.

1.1.2   Maximum likelihood estimator is biased

Theorem: Let $x = \{x_1, \ldots, x_n\}$ be a set of independent normally distributed ($\rightarrow$ Definition II/3.2.1) observations with unknown mean ($\rightarrow$ Definition I/1.5.1) μ and variance ($\rightarrow$ Definition I/1.6.1) σ^2:

$$x_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \ . \tag{1}$$

Then,

1) the maximum likelihood estimator ($\rightarrow$ Definition I/4.1.3) of σ^2 is

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^{n} \left(x_i - \bar{x}\right)^2 \tag{2}$$

where

$$\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i \tag{3}$$

2) and $\hat{\sigma}^2$ is a biased estimator ($\rightarrow$ Definition "est-unb") of σ^2

$$\mathbb{E}\left[\hat{\sigma}^2\right] \neq \sigma^2 \ , \tag{4}$$

more precisely:

$$\mathbb{E}\left[\hat{\sigma}^2\right] = \frac{n-1}{n}\sigma^2 \ . \tag{5}$$

Proof:

1) This is equivalent to the maximum likelihood estimator for the univariate Gaussian with unknown variance ($\rightarrow$ Proof III/1.1.2) and a special case of the maximum likelihood estimator for multiple linear regression ($\rightarrow$ Proof III/1.3.15) in which $y = x$, $X = 1_n$ and $\hat{\beta} = \bar{x}$:

$$
\begin{aligned}
\hat{\sigma}^2 &= \frac{1}{n}(y - X\hat{\beta})^{\mathrm{T}}(y - X\hat{\beta}) \\
&= \frac{1}{n}(x - 1_n\bar{x})^{\mathrm{T}}(x - 1_n\bar{x}) \\
&= \frac{1}{n}\sum_{i=1}^{n}(x_i - \bar{x})^2 \ .
\end{aligned}
\tag{6}
$$

2) The expectation ($\rightarrow$ Definition I/1.5.1) of the maximum likelihood estimator ($\rightarrow$ Definition I/4.1.3) can be developed as follows:

$$
\begin{aligned}
\mathbb{E}\left[\hat{\sigma}^2\right] &= \mathbb{E}\left[\frac{1}{n}\sum_{i=1}^{n}(x_i - \bar{x})^2\right] \\
&= \frac{1}{n}\mathbb{E}\left[\sum_{i=1}^{n}(x_i - \bar{x})^2\right] \\
&= \frac{1}{n}\mathbb{E}\left[\sum_{i=1}^{n}\left(x_i^2 - 2x_i\bar{x} + \bar{x}^2\right)\right] \\
&= \frac{1}{n}\mathbb{E}\left[\sum_{i=1}^{n}x_i^2 - 2\sum_{i=1}^{n}x_i\bar{x} + \sum_{i=1}^{n}\bar{x}^2\right] \\
&= \frac{1}{n}\mathbb{E}\left[\sum_{i=1}^{n}x_i^2 - 2n\bar{x}^2 + n\bar{x}^2\right] \\
&= \frac{1}{n}\mathbb{E}\left[\sum_{i=1}^{n}x_i^2 - n\bar{x}^2\right] \\
&= \frac{1}{n}\left(\sum_{i=1}^{n}\mathbb{E}\left[x_i^2\right] - n\mathbb{E}\left[\bar{x}^2\right]\right) \\
&= \frac{1}{n}\sum_{i=1}^{n}\mathbb{E}\left[x_i^2\right] - \mathbb{E}\left[\bar{x}^2\right]
\end{aligned}
\tag{7}
$$

Due to the partition of variance into expected values ($\rightarrow$ Proof I/1.6.3)

$$
\mathrm{Var}(X) = \mathbb{E}(X^2) - \mathbb{E}(X)^2 \ ,
\tag{8}
$$

we have

$$
\begin{aligned}
\mathrm{Var}(x_i) &= \mathbb{E}(x_i^2) - \mathbb{E}(x_i)^2 \\
\mathrm{Var}(\bar{x}) &= \mathbb{E}(\bar{x}^2) - \mathbb{E}(\bar{x})^2 \ ,
\end{aligned}
\tag{9}
$$

such that (7) becomes

$$
\mathbb{E}\left[\hat{\sigma}^2\right] = \frac{1}{n}\sum_{i=1}^{n}\left(\mathrm{Var}(x_i) + \mathbb{E}(x_i)^2\right) - \left(\mathrm{Var}(\bar{x}) + \mathbb{E}(\bar{x})^2\right) \ .
\tag{10}
$$

From (1), it follows that

$$\mathbb{E}(x_i) = \mu \quad \text{and} \quad \mathrm{Var}(x_i) = \sigma^2 \ . \tag{11}$$

The expectation ($\to$ Definition I/1.5.1) of $\bar{x}$ given by (3) is

$$
\begin{aligned}
\mathbb{E}\left[\bar{x}\right] &= \mathbb{E}\left[\frac{1}{n}\sum_{i=1}^{n} x_i\right] = \frac{1}{n}\sum_{i=1}^{n}\mathbb{E}\left[x_i\right] \\
&\overset{(11)}{=} \frac{1}{n}\sum_{i=1}^{n}\mu = \frac{1}{n}\cdot n\cdot\mu \\
&= \mu \ .
\end{aligned}
\tag{12}
$$

The variance of $\bar{x}$ given by (3) is

$$
\begin{aligned}
\mathrm{Var}\left[\bar{x}\right] &= \mathrm{Var}\left[\frac{1}{n}\sum_{i=1}^{n} x_i\right] = \frac{1}{n^2}\sum_{i=1}^{n}\mathrm{Var}\left[x_i\right] \\
&\overset{(11)}{=} \frac{1}{n^2}\sum_{i=1}^{n}\sigma^2 = \frac{1}{n^2}\cdot n\cdot\sigma^2 \\
&= \frac{1}{n}\sigma^2 \ .
\end{aligned}
\tag{13}
$$

Plugging (11), (12) and (13) into (10), we have

$$
\begin{aligned}
\mathbb{E}\left[\hat{\sigma}^2\right] &= \frac{1}{n}\sum_{i=1}^{n}\left(\sigma^2 + \mu^2\right) - \left(\frac{1}{n}\sigma^2 + \mu^2\right) \\
\mathbb{E}\left[\hat{\sigma}^2\right] &= \frac{1}{n}\cdot n\cdot\left(\sigma^2 + \mu^2\right) - \left(\frac{1}{n}\sigma^2 + \mu^2\right) \\
\mathbb{E}\left[\hat{\sigma}^2\right] &= \sigma^2 + \mu^2 - \frac{1}{n}\sigma^2 - \mu^2 \\
\mathbb{E}\left[\hat{\sigma}^2\right] &= \frac{n-1}{n}\sigma^2
\end{aligned}
\tag{14}
$$

which proves the bias ($\to$ Definition "est-unb") given by (5).

1.1.3   Construction of unbiased estimator

Theorem: Let $x = \{x_1, \ldots, x_n\}$ be a set of independent normally distributed ($\to$ Definition II/3.2.1) observations with unknown mean ($\to$ Definition I/1.5.1) μ and variance ($\to$ Definition I/1.6.1) σ^2:

$$x_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(\mu, \sigma^2), \quad i = 1, \ldots, n \,. \tag{1}$$

An unbiased estimator ($\rightarrow$ Definition "est-unb") of σ^2 is given by

$$\hat{\sigma}^2_{\text{unb}} = \frac{1}{n-1} \sum_{i=1}^{n} (x_i - \bar{x})^2 \,. \tag{2}$$

Proof: It can be shown that ($\rightarrow$ Proof IV/1.1.2) the maximum likelihood estimator ($\rightarrow$ Definition I/4.1.3) of σ^2

$$\hat{\sigma}^2_{\text{MLE}} = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^2 \tag{3}$$

is a biased estimator ($\rightarrow$ Definition "est-unb") in the sense that

$$\mathbb{E}\left[\hat{\sigma}^2_{\text{MLE}}\right] = \frac{n-1}{n} \sigma^2 \,. \tag{4}$$

From (4), it follows that

$$\begin{aligned}
\mathbb{E}\left[\frac{n}{n-1} \hat{\sigma}^2_{\text{MLE}}\right] &= \frac{n}{n-1} \mathbb{E}\left[\hat{\sigma}^2_{\text{MLE}}\right] \\
&\overset{(4)}{=} \frac{n}{n-1} \cdot \frac{n-1}{n} \sigma^2 \\
&= \sigma^2 \,,
\end{aligned} \tag{5}$$

such that an unbiased estimator ($\rightarrow$ Definition "est-unb") can be constructed as

$$\begin{aligned}
\hat{\sigma}^2_{\text{unb}} &= \frac{n}{n-1} \hat{\sigma}^2_{\text{MLE}} \\
&\overset{(3)}{=} \frac{n}{n-1} \cdot \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^2 \\
&= \frac{1}{n-1} \sum_{i=1}^{n} (x_i - \bar{x})^2 \,.
\end{aligned} \tag{6}$$

1.2 R-squared

1.2.1 Definition

Definition: Let there be a linear regression model ($\rightarrow$ Definition III/1.3.1) with independent ($\rightarrow$ Definition I/1.2.6) observations

$$y = X\beta + \varepsilon, \ \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \tag{1}$$

with measured data y, known design matrix X as well as unknown regression coefficients β and noise variance σ^2.

Then, the proportion of the variance of the dependent variable y ("total variance ($\rightarrow$ Definition III/1.3.4)") that can be predicted from the independent variables X ("explained variance ($\rightarrow$ Definition III/1.3.5)") is called "coefficient of determination", "R-squared" or R^2.

Sources:
- Wikipedia (2020): "Coefficient of determination"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-02-25; URL: https://en.wikipedia.org/wiki/Mean_squared_error#Proof_of_variance_ and_bias_relationship.

Metadata: ID: D21 | shortcut: rsq | author: JoramSoch | date: 2020-02-25, 11:41.

1.2.2   Derivation of R² and adjusted R²

Theorem: Given a linear regression model ($\rightarrow$ Definition III/1.3.1)

$$y = X\beta + \varepsilon, \ \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \tag{1}$$

with n independent observations and p independent variables,
1) the coefficient of determination ($\rightarrow$ Definition IV/1.2.1) is given by

$$R^2 = 1 - \frac{\text{RSS}}{\text{TSS}} \tag{2}$$

2) the adjusted coefficient of determination is

$$R^2_{\text{adj}} = 1 - \frac{\text{RSS}/(n-p)}{\text{TSS}/(n-1)} \tag{3}$$

where the residual ($\rightarrow$ Definition III/1.3.6) and total sum of squares ($\rightarrow$ Definition III/1.3.4) are

$$\begin{aligned}
\text{RSS} &= \sum_{i=1}^{n}(y_i - \hat{y}_i)^2, \quad \hat{y} = X\hat{\beta} \\
\text{TSS} &= \sum_{i=1}^{n}(y_i - \bar{y})^2 \ , \quad \bar{y} = \frac{1}{n}\sum_{i=1}^{n} y_i
\end{aligned} \tag{4}$$

where X is the $n \times p$ design matrix and $\hat{\beta}$ are the ordinary least squares ($\rightarrow$ Proof III/1.3.2) estimates.

Proof: The coefficient of determination R^2 is defined as ($\rightarrow$ Definition IV/1.2.1) the proportion of the variance explained by the independent variables, relative to the total variance in the data.

1) If we define the explained sum of squares ($\rightarrow$ Definition III/1.3.5) as

$$\text{ESS} = \sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2 \ , \tag{5}$$

then R^2 is given by

$$R^2 = \frac{\text{ESS}}{\text{TSS}} \,. \tag{6}$$

which is equal to

$$R^2 = \frac{\text{TSS} - \text{RSS}}{\text{TSS}} = 1 - \frac{\text{RSS}}{\text{TSS}} \,, \tag{7}$$

because ($\to$ Proof III/1.3.7) TSS = ESS + RSS.

2) Using (4), the coefficient of determination can be also written as:

$$R^2 = 1 - \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2} = 1 - \frac{\frac{1}{n}\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\frac{1}{n}\sum_{i=1}^n (y_i - \bar{y})^2} \,. \tag{8}$$

If we replace the variance estimates by their unbiased estimators ($\to$ Proof IV/1.1.3), we obtain

$$R^2_{\text{adj}} = 1 - \frac{\frac{1}{n-p}\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\frac{1}{n-1}\sum_{i=1}^n (y_i - \bar{y})^2} = 1 - \frac{\text{RSS}/\text{df}_r}{\text{TSS}/\text{df}_t} \tag{9}$$

where $\text{df}_r = n - p$ and $\text{df}_t = n - 1$ are the residual and total degrees of freedom ($\to$ Definition "dof").

This gives the adjusted R^2 which adjusts R^2 for the number of explanatory variables.

Sources:
- Wikipedia (2019): "Coefficient of determination"; in: *Wikipedia, the free encyclopedia*, retrieved on 2019-12-06; URL: https://en.wikipedia.org/wiki/Coefficient_of_determination#Adjusted_R2.

Metadata: ID: P8 | shortcut: rsq-der | author: JoramSoch | date: 2019-12-06, 11:19.

1.2.3 Relationship to maximum log-likelihood

Theorem: Given a linear regression model ($\to$ Definition III/1.3.1) with independent observations

$$y = X\beta + \varepsilon, \ \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \,, \tag{1}$$

the coefficient of determination ($\to$ Definition IV/1.2.1) can be expressed in terms of the maximum log-likelihood ($\to$ Definition I/4.1.4) as

$$R^2 = 1 - (\exp[\Delta\text{MLL}])^{-2/n} \tag{2}$$

where n is the number of observations and ΔMLL is the difference in maximum log-likelihood between the model given by (1) and a linear regression model with only a constant regressor.

Proof: First, we express the maximum log-likelihood ($\to$ Definition I/4.1.4) (MLL) of a linear regression model in terms of its residual sum of squares ($\to$ Definition III/1.3.6) (RSS). The model in (1) implies the following log-likelihood function ($\to$ Definition I/4.1.2)

$$\text{LL}(\beta, \sigma^2) = \log p(y|\beta, \sigma^2) = -\frac{n}{2}\log(2\pi\sigma^2) - \frac{1}{2\sigma^2}(y - X\beta)^{\text{T}}(y - X\beta) \,, \tag{3}$$

such that maximum likelihood estimates are ($\to$ Proof III/1.3.15)

$$\hat{\beta} = (X^{\mathrm{T}}X)^{-1}X^{\mathrm{T}}y \tag{4}$$

$$\hat{\sigma}^2 = \frac{1}{n}(y - X\hat{\beta})^{\mathrm{T}}(y - X\hat{\beta}) \tag{5}$$

and the residual sum of squares ($\to$ Definition III/1.3.6) is

$$\mathrm{RSS} = \sum_{i=1}^{n} \hat{\varepsilon}_i = \hat{\varepsilon}^{\mathrm{T}}\hat{\varepsilon} = (y - X\hat{\beta})^{\mathrm{T}}(y - X\hat{\beta}) = n \cdot \hat{\sigma}^2 \ . \tag{6}$$

Since $\hat{\beta}$ and $\hat{\sigma}^2$ are maximum likelihood estimates ($\to$ Definition I/4.1.3), plugging them into the log-likelihood function gives the maximum log-likelihood:

$$\mathrm{MLL} = \mathrm{LL}(\hat{\beta}, \hat{\sigma}^2) = -\frac{n}{2}\log(2\pi\hat{\sigma}^2) - \frac{1}{2\hat{\sigma}^2}(y - X\hat{\beta})^{\mathrm{T}}(y - X\hat{\beta}) \ . \tag{7}$$

With (6) for the first $\hat{\sigma}^2$ and (5) for the second $\hat{\sigma}^2$, the MLL becomes

$$\mathrm{MLL} = -\frac{n}{2}\log(\mathrm{RSS}) - \frac{n}{2}\log\left(\frac{2\pi}{n}\right) - \frac{n}{2} \ . \tag{8}$$

Second, we establish the relationship between maximum log-likelihood (MLL) and coefficient of determination (R^2). Consider the two models

$$\begin{aligned} m_0 &: \ X_0 = 1_n \\ m_1 &: \ X_1 = X \end{aligned} \tag{9}$$

For m_1, the residual sum of squares is given by (6); and for m_0, the residual sum of squares is equal to the total sum of squares ($\to$ Definition III/1.3.4):

$$\mathrm{TSS} = \sum_{i=1}^{n}(y_i - \bar{y})^2 \ . \tag{10}$$

Using (8), we can therefore write

$$\Delta\mathrm{MLL} = \mathrm{MLL}(m_1) - \mathrm{MLL}(m_0) = -\frac{n}{2}\log(\mathrm{RSS}) + \frac{n}{2}\log(\mathrm{TSS}) \ . \tag{11}$$

Exponentiating both sides of the equation, we have:

$$\begin{aligned} \exp[\Delta\mathrm{MLL}] &= \exp\left[-\frac{n}{2}\log(\mathrm{RSS}) + \frac{n}{2}\log(\mathrm{TSS})\right] \\ &= (\exp\left[\log(\mathrm{RSS}) - \log(\mathrm{TSS})\right])^{-n/2} \\ &= \left(\frac{\exp[\log(\mathrm{RSS})]}{\exp[\log(\mathrm{TSS})]}\right)^{-n/2} \\ &= \left(\frac{\mathrm{RSS}}{\mathrm{TSS}}\right)^{-n/2} \ . \end{aligned} \tag{12}$$

Taking both sides to the power of $-2/n$ and subtracting from 1, we have

$$(\exp[\Delta\text{MLL}])^{-2/n} = \frac{\text{RSS}}{\text{TSS}}$$

$$1 - (\exp[\Delta\text{MLL}])^{-2/n} = 1 - \frac{\text{RSS}}{\text{TSS}} = R^2 \tag{13}$$

which proves the identity given above.

1.3 Signal-to-noise ratio

1.3.1 Definition

Definition: Let there be a linear regression model ($\to$ Definition III/1.3.1) with independent ($\to$ Definition I/1.2.6) observations

$$y = X\beta + \varepsilon, \ \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \tag{1}$$

with measured data y, known design matrix X as well as unknown regression coefficients β and noise variance σ^2.

Given estimated regression coefficients ($\to$ Proof III/1.3.15) $\hat{\beta}$ and residual variance ($\to$ Definition IV/1.1.1) $\hat{\sigma}^2$, the signal-to-noise ratio (SNR) is defined as the ratio of estimated signal variance to estimated noise variance:

$$\text{SNR} = \frac{\text{Var}(X\hat{\beta})}{\hat{\sigma}^2} \ . \tag{2}$$

Sources:
- Soch J, Allefeld C (2018): "MACS – a new SPM toolbox for model assessment, comparison and selection"; in: *Journal of Neuroscience Methods*, vol. 306, pp. 19-31, eq. 6; URL: https://www.sciencedirect.com/science/article/pii/S0165027018301468; DOI: 10.1016/j.jneumeth.2018.05.017.

Metadata: ID: D22 | shortcut: snr | author: JoramSoch | date: 2020-02-25, 12:01.

1.3.2 Relationship with R²

Theorem: Let there be a linear regression model ($\to$ Definition III/1.3.1) with independent ($\to$ Definition I/1.2.6) observations

$$y = X\beta + \varepsilon, \ \varepsilon_i \overset{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma^2) \tag{1}$$

and parameter estimates ($\to$ Definition "est") obtained with ordinary least squares ($\to$ Proof III/1.3.2)

$$\hat{\beta} = (X^{\text{T}}X)^{-1}X^{\text{T}}y \ . \tag{2}$$

Then, the signal-to noise ratio ($\to$ Definition IV/1.3.1) can be expressed in terms of the coefficient of determination ($\to$ Definition IV/1.2.1)

$$\text{SNR} = \frac{R^2}{1 - \text{R}^2} \tag{3}$$

and vice versa

$$R^2 = \frac{\text{SNR}}{1 + \text{SNR}} \ , \tag{4}$$

if the predicted signal mean is equal to the actual signal mean.

Proof: The signal-to-noise ratio (SNR) is defined as ($\to$ Definition IV/1.3.1)

$$\text{SNR} = \frac{\text{Var}(X\hat{\beta})}{\hat{\sigma}^2} = \frac{\text{Var}(\hat{y})}{\hat{\sigma}^2} \ . \tag{5}$$

Writing out the variances, we have

$$\text{SNR} = \frac{\frac{1}{n}\sum_{i=1}^{n}(\hat{y}_i - \bar{\hat{y}})^2}{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} = \frac{\sum_{i=1}^{n}(\hat{y}_i - \bar{\hat{y}})^2}{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \ . \tag{6}$$

Note that it is irrelevant whether we use the biased estimator of the variance ($\to$ Proof IV/1.1.2) (dividing by n) or the unbiased estimator fo the variance ($\to$ Proof IV/1.1.3) (dividing by $n - 1$), because the relevant terms cancel out.

If the predicted signal mean is equal to the actual signal mean – which is the case when variable regressors in X have mean zero, such that they are orthogonal to a constant regressor in X –, this means that $\bar{\hat{y}} = \bar{y}$, such that

$$\text{SNR} = \frac{\sum_{i=1}^{n}(\hat{y}_i - \bar{y})^2}{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \ . \tag{7}$$

Then, the SNR can be written in terms of the explained ($\to$ Definition III/1.3.5), residual ($\to$ Definition III/1.3.6) and total sum of squares ($\to$ Definition III/1.3.4):

$$\text{SNR} = \frac{\text{ESS}}{\text{RSS}} = \frac{\text{ESS/TSS}}{\text{RSS/TSS}} \ . \tag{8}$$

With the derivation of the coefficient of determination ($\to$ Proof IV/1.2.2), this becomes

$$\text{SNR} = \frac{R^2}{1 - R^2} \ . \tag{9}$$

Rearranging this equation for the coefficient of determination ($\to$ Definition IV/1.2.1), we have

$$R^2 = \frac{\text{SNR}}{1 + \text{SNR}} \ , \tag{10}$$

2 Classical information criteria

2.1 Akaike information criterion

2.1.1 Definition

Definition: Let m be a generative model ($\rightarrow$ Definition I/5.1.1) with likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, m)$ and maximum likelihood estimates ($\rightarrow$ Definition I/4.1.3)

$$\hat{\theta} = \arg\max_{\theta} \log p(y|\theta, m) . \tag{1}$$

Then, the Akaike information criterion (AIC) of this model is defined as

$$\mathrm{AIC}(m) = -2 \log p(y|\hat{\theta}, m) + 2\,p \tag{2}$$

where p is the number of free parameters estimated via (1).

Sources:
- Akaike H (1974): "A New Look at the Statistical Model Identification"; in: *IEEE Transactions on Automatic Control*, vol. AC-19, no. 6, pp. 716-723; URL: https://ieeexplore.ieee.org/document/1100705; DOI: 10.1109/TAC.1974.1100705.

Metadata: ID: D23 | shortcut: aic | author: JoramSoch | date: 2020-02-25, 12:31.

2.2 Bayesian information criterion

2.2.1 Definition

Definition: Let m be a generative model ($\rightarrow$ Definition I/5.1.1) with likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, m)$ and maximum likelihood estimates ($\rightarrow$ Definition I/4.1.3)

$$\hat{\theta} = \arg\max_{\theta} \log p(y|\theta, m) . \tag{1}$$

Then, the Bayesian information criterion (BIC) of this model is defined as

$$\mathrm{BIC}(m) = -2 \log p(y|\hat{\theta}, m) + p \log n \tag{2}$$

where n is the number of data points and p is the number of free parameters estimated via (1).

Sources:
- Schwarz G (1978): "Estimating the Dimension of a Model"; in: *The Annals of Statistics*, vol. 6, no. 2, pp. 461-464; URL: https://www.jstor.org/stable/2958889.

Metadata: ID: D24 | shortcut: bic | author: JoramSoch | date: 2020-02-25, 12:21.

2.2.2 Derivation

Theorem: Let $p(y|\theta, m)$ be the likelihood function ($\rightarrow$ Definition I/5.1.2) of a generative model ($\rightarrow$ Definition I/5.1.1) $m \in \mathcal{M}$ with model parameters $\theta \in \Theta$ describing measured data $y \in \mathbb{R}^n$.

Let $p(\theta|m)$ be a prior distribution ($\to$ Definition I/5.1.3) on the model parameters. Assume that likelihood function and prior density are twice differentiable.

Then, as the number of data points goes to infinity, an approximation to the log-marginal likelihood ($\to$ Definition I/5.1.9) $\log p(y|m)$, up to constant terms not depending on the model, is given by the Bayesian information criterion ($\to$ Definition IV/2.2.1) (BIC) as

$$-2 \log p(y|m) \approx \text{BIC}(m) = -2 \log p(y|\hat{\theta}, m) + p \log n \tag{1}$$

where $\hat{\theta}$ is the maximum likelihood estimator ($\to$ Definition I/4.1.3) (MLE) of θ, n is the number of data points and p is the number of model parameters.

Proof: Let $\text{LL}(\theta)$ be the log-likelihood function ($\to$ Definition I/4.1.2)

$$\text{LL}(\theta) = \log p(y|\theta, m) \tag{2}$$

and define the functions g and h as follows:

$$\begin{aligned} g(\theta) &= p(\theta|m) \\ h(\theta) &= \frac{1}{n} \text{LL}(\theta) \, . \end{aligned} \tag{3}$$

Then, the marginal likelihood ($\to$ Definition I/5.1.9) can be written as follows:

$$\begin{aligned} p(y|m) &= \int_{\Theta} p(y|\theta, m) \, p(\theta|m) \, \mathrm{d}\theta \\ &= \int_{\Theta} \exp\left[n \, h(\theta)\right] g(\theta) \, \mathrm{d}\theta \, . \end{aligned} \tag{4}$$

This is an integral suitable for Laplace approximation which states that

$$\int_{\Theta} \exp\left[n \, h(\theta)\right] g(\theta) \, \mathrm{d}\theta = \left(\sqrt{\frac{2\pi}{n}}\right)^{p} \exp\left[n \, h(\theta_0)\right] \left(g(\theta_0) \, |J(\theta_0)|^{-1/2} + O(1/n)\right) \tag{5}$$

where θ_0 is the value that maximizes $h(\theta)$ and $J(\theta_0)$ is the Hessian matrix evaluated at θ_0. In our case, we have $h(\theta) = 1/n \, \text{LL}(\theta)$ such that θ_0 is the maximum likelihood estimator $\hat{\theta}$:

$$\hat{\theta} = \arg\max_{\theta} \text{LL}(\theta) \, . \tag{6}$$

With this, (5) can be applied to (4) using (3) to give:

$$p(y|m) \approx \left(\sqrt{\frac{2\pi}{n}}\right)^{p} p(y|\hat{\theta}, m) \, p(\hat{\theta}|m) \left|J(\hat{\theta})\right|^{-1/2} \, . \tag{7}$$

Logarithmizing and multiplying with -2, we have:

$$-2 \log p(y|m) \approx -2 \text{LL}(\hat{\theta}) + p \log n - p \log(2\pi) - 2 \log p(\hat{\theta}|m) + \log \left|J(\hat{\theta})\right| \, . \tag{8}$$

As $n \to \infty$, the last three terms are $O_p(1)$ and can therefore be ignored when comparing between models $\mathcal{M} = \{m_1, \ldots, m_M\}$ and using $p(y|m_j)$ to compute posterior model probabilies ($\to$ Definition IV/3.5.1) $p(m_j|y)$. With that, the BIC is given as

$$\mathrm{BIC}(m) = -2\log p(y|\hat{\theta}, m) + p \log n \ . \tag{9}$$

2.3 Deviance information criterion

2.3.1 Definition

Definition: Let m be a generative model ($\rightarrow$ Definition I/5.1.1) with likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, m)$ and prior distribution ($\rightarrow$ Definition I/5.1.3) $p(\theta|m)$. Together, likelihood function and prior distribution imply a posterior distribution ($\rightarrow$ Definition I/5.1.7) $p(\theta|y, m)$.
Define the posterior expected log-likelihood ($\rightarrow$ Definition I/4.1.2) (PLL)

$$\mathrm{PLL}(m) = \langle \log p(y|\theta, m) \rangle_{\theta|y} \tag{1}$$

and the log-likelihood ($\rightarrow$ Definition I/4.1.2) at the posterior expectation (LLP)

$$\mathrm{LLP}(m) = \log p(y| \langle \theta \rangle_{\theta|y}, m) \tag{2}$$

where $\langle \cdot \rangle_{\theta|y}$ denotes an expectation across the posterior distribution.
Then, the deviance information criterion (DIC) of the model is defined as

$$\mathrm{DIC}(m) = -2\,\mathrm{LLP}(m) + 2\,p_D \quad \text{or} \quad \mathrm{DIC}(m) = -2\,\mathrm{PLL}(m) + p_D \tag{3}$$

where the "effective number of parameters" p_D is given by

$$p_D = -2\,\mathrm{PLL}(m) + 2\,\mathrm{LLP}(m) \ . \tag{4}$$

3 Bayesian model selection

3.1 Log model evidence

3.1.1 Definition

Definition: Let m be a generative model ($\rightarrow$ Definition I/5.1.1) with likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, m)$ and prior distribution ($\rightarrow$ Definition I/5.1.3) $p(\theta|m)$. Then, the log model evidence (LME) of this model is defined as the logarithm of the marginal likelihood ($\rightarrow$ Definition I/5.1.9):

$$\text{LME}(m) = \log p(y|m) \,. \tag{1}$$

Sources:

- Soch J, Allefeld C (2018): "MACS – a new SPM toolbox for model assessment, comparison and selection"; in: *Journal of Neuroscience Methods*, vol. 306, pp. 19-31, eq. 13; URL: https://www.sciencedirect.com/science/article/pii/S0165027018301468; DOI: 10.1016/j.jneumeth.2018.05.017.

Metadata: ID: D26 | shortcut: lme | author: JoramSoch | date: 2020-02-25, 12:56.

3.1.2 Derivation

Theorem: Let $p(y|\theta, m)$ be a likelihood function ($\rightarrow$ Definition I/5.1.2) of a generative model ($\rightarrow$ Definition I/5.1.1) m for making inferences on model parameters θ given measured data y. Moreover, let $p(\theta|m)$ be a prior distribution ($\rightarrow$ Definition I/5.1.3) on model parameters θ. Then, the log model evidence ($\rightarrow$ Definition IV/3.1.1) (LME), also called marginal log-likelihood,

$$\text{LME}(m) = \log p(y|m) \,, \tag{1}$$

can be expressed
1) as

$$\text{LME}(m) = \log \int p(y|\theta, m) \, p(\theta|m) \, \mathrm{d}\theta \tag{2}$$

2) or

$$\text{LME}(m) = \log p(y|\theta, m) + \log p(\theta|m) - \log p(\theta|y, m) \,. \tag{3}$$

Proof:
1) The first expression is a simple consequence of the law of marginal probability ($\rightarrow$ Definition I/1.2.3) for continuous variables according to which

$$p(y|m) = \int p(y|\theta, m) \, p(\theta|m) \, \mathrm{d}\theta \tag{4}$$

which, when logarithmized, gives

$$\text{LME}(m) = \log p(y|m) = \log \int p(y|\theta, m) \, p(\theta|m) \, \mathrm{d}\theta \,. \tag{5}$$

2) The second expression can be derived from Bayes' theorem ($\rightarrow$ Proof I/5.3.1) which makes a statement about the posterior distribution ($\rightarrow$ Definition I/5.1.7):

$$p(\theta|y, m) = \frac{p(y|\theta, m)\, p(\theta|m)}{p(y|m)} \; . \tag{6}$$

Rearranging for $p(y|m)$ and logarithmizing, we have:

$$
\begin{aligned}
\text{LME}(m) = \log p(y|m) &= \log \frac{p(y|\theta, m)\, p(\theta|m)}{p(\theta|y, m)} \\
&= \log p(y|\theta, m) + \log p(\theta|m) - \log p(\theta|y, m) \; .
\end{aligned}
\tag{7}
$$

- original work

Metadata: ID: P13 | shortcut: lme-der | author: JoramSoch | date: 2020-01-06, 21:27.

3.1.3 Partition into accuracy and complexity

Theorem: The log model evidence ($\rightarrow$ Definition IV/3.1.1) can be partitioned into accuracy and complexity

$$\text{LME}(m) = \text{Acc}(m) - \text{Com}(m) \tag{1}$$

where the accuracy term is the posterior ($\rightarrow$ Definition I/5.1.7) expectation ($\rightarrow$ Proof I/1.5.9) of the log-likelihood function ($\rightarrow$ Definition I/4.1.2)

$$\text{Acc}(m) = \langle \log p(y|\theta, m) \rangle_{p(\theta|y,m)} \tag{2}$$

and the complexity penalty is the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) of posterior ($\rightarrow$ Definition I/5.1.7) from prior ($\rightarrow$ Definition I/5.1.3)

$$\text{Com}(m) = \text{KL}\left[p(\theta|y, m) \,\|\, p(\theta|m) \right] \; . \tag{3}$$

Proof: We consider Bayesian inference on data ($\rightarrow$ Definition "data") y using model ($\rightarrow$ Definition I/5.1.1) m with parameters θ. Then, Bayes' theorem ($\rightarrow$ Proof I/5.3.1) makes a statement about the posterior distribution ($\rightarrow$ Definition I/5.1.7), i.e. the probability of parameters, given the data and the model:

$$p(\theta|y, m) = \frac{p(y|\theta, m)\, p(\theta|m)}{p(y|m)} \; . \tag{4}$$

Rearranging this for the model evidence ($\rightarrow$ Proof IV/3.1.2), we have:

$$p(y|m) = \frac{p(y|\theta, m)\, p(\theta|m)}{p(\theta|y, m)} \; . \tag{5}$$

Logarthmizing both sides of the equation, we obtain:

$$\log p(y|m) = \log p(y|\theta, m) - \log \frac{p(\theta|y, m)}{p(\theta|m)} \; . \tag{6}$$

Now taking the expectation over the posterior distribution yields:

$$\log p(y|m) = \int p(\theta|y, m) \log p(y|\theta, m) \, \mathrm{d}\theta - \int p(\theta|y, m) \log \frac{p(\theta|y, m)}{p(\theta|m)} \, \mathrm{d}\theta \,. \tag{7}$$

By definition, the left-hand side is the log model evidence and the terms on the right-hand side correspond to the posterior expectation of the log-likelihood function and the Kullback-Leibler divergence of posterior from prior

$$\mathrm{LME}(m) = \langle \log p(y|\theta, m) \rangle_{p(\theta|y,m)} - \mathrm{KL}\left[p(\theta|y, m) \,||\, p(\theta|m)\right] \tag{8}$$

which proofs the partition given by (1).

Metadata: ID: P3 | shortcut: lme-anc | author: JoramSoch | date: 2019-09-27, 16:13.

3.1.4 Uniform-prior log model evidence

Definition: Assume a generative model ($\rightarrow$ Definition I/5.1.1) m with likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, m)$ and a uniform ($\rightarrow$ Definition I/5.2.2) prior distribution ($\rightarrow$ Definition I/5.1.3) $p_{\mathrm{uni}}(\theta|m)$. Then, the log model evidence ($\rightarrow$ Definition IV/3.1.1) of this model is called "log model evidence with uniform prior" or "uniform-prior log model evidence" (upLME):

$$\mathrm{upLME}(m) = \log \int p(y|\theta, m) \, p_{\mathrm{uni}}(\theta|m) \, \mathrm{d}\theta \,. \tag{1}$$

Sources:
- Wikipedia (2020): "Lindley's paradox"; in: *Wikipedia, the free encyclopedia*, retrieved on 2020-11-25; URL: https://en.wikipedia.org/wiki/Lindley%27s_paradox#Bayesian_approach.

Metadata: ID: D113 | shortcut: uplme | author: JoramSoch | date: 2020-11-25, 07:28.

3.1.5 Cross-validated log model evidence

Definition: Let there be a data set ($\rightarrow$ Definition "data") y with mutually exclusive and collectively exhaustive subsets $y_1, \ldots, y_S$. Assume a generative model ($\rightarrow$ Definition I/5.1.1) m with model parameters θ implying a likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, m)$ and a non-informative ($\rightarrow$ Definition I/5.2.3) prior density ($\rightarrow$ Definition I/5.1.3) $p_{\mathrm{ni}}(\theta|m)$.
Then, the cross-validated log model evidence of m is given by

$$\mathrm{cvLME}(m) = \sum_{i=1}^{S} \log \int p(y_i|\theta, m) \, p(\theta|y_{\neg i}, m) \, \mathrm{d}\theta \tag{1}$$

where $y_{\neg i} = \bigcup_{j \neq i} y_j$ is the union of all data subsets except y_i and $p(\theta|y_{\neg i}, m)$ is the posterior distribution ($\rightarrow$ Definition I/5.1.7) obtained from $y_{\neg i}$ when using the prior distribution ($\rightarrow$ Definition I/5.1.3) $p_{\mathrm{ni}}(\theta|m)$:

$$p(\theta|y_{\neg i}, m) = \frac{p(y_{\neg i}|\theta, m)\, p_{\mathrm{ni}}(\theta|m)}{p(y_{\neg i}|m)}\ . \tag{2}$$

3.1.6 Empirical Bayesian log model evidence

Definition: Let m be a generative model ($\rightarrow$ Definition I/5.1.1) with model parameters θ and hyper-parameters λ implying the likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, \lambda, m)$ and prior distribution ($\rightarrow$ Definition I/5.1.3) $p(\theta|\lambda, m)$. Then, the Empirical Bayesian ($\rightarrow$ Definition I/5.3.3) log model evidence ($\rightarrow$ Definition IV/3.1.1) is the logarithm of the marginal likelihood ($\rightarrow$ Definition I/5.1.9), maximized with respect to the hyper-parameters:

$$\mathrm{ebLME}(m) = \log p(y|\hat{\lambda}, m) \tag{1}$$

where

$$p(y|\lambda, m) = \int p(y|\theta, \lambda, m)\, (\theta|\lambda, m)\, \mathrm{d}\theta \tag{2}$$

and ($\rightarrow$ Definition I/5.2.7)

$$\hat{\lambda} = \arg\max_{\lambda} \log p(y|\lambda, m)\ . \tag{3}$$

Metadata: ID: D114 | shortcut: eblme | author: JoramSoch | date: 2020-11-25, 07:43.

3.1.7 Variational Bayesian log model evidence

Definition: Let m be a generative model ($\rightarrow$ Definition I/5.1.1) with model parameters θ implying the likelihood function ($\rightarrow$ Definition I/5.1.2) $p(y|\theta, m)$ and prior distribution ($\rightarrow$ Definition I/5.1.3) $p(\theta|m)$. Moreover, assume an approximate ($\rightarrow$ Definition I/5.3.4) posterior distribution ($\rightarrow$ Definition I/5.1.7) $q(\theta)$. Then, the Variational Bayesian ($\rightarrow$ Definition I/5.3.4) log model evidence ($\rightarrow$ Definition IV/3.1.1), also referred to as the "negative free energy", is the expectation of the log-likelihood function ($\rightarrow$ Definition I/4.1.2) with respect to the approximate posterior, minus the Kullback-Leibler divergence ($\rightarrow$ Definition I/2.5.1) between approximate posterior and the prior distribution:

$$\text{vbLME}(m) = \langle \log p(y|\theta, m) \rangle_{q(\theta)} - \text{KL}\left[q(\theta)||p(\theta|m)\right] \tag{1}$$

where

$$\langle \log p(y|\theta, m) \rangle_{q(\theta)} = \int q(\theta) \log p(y|\theta, m)\, \mathrm{d}\theta \tag{2}$$

and

$$\text{KL}\left[q(\theta)||p(\theta|m)\right] = \int q(\theta) \log \frac{q(\theta)}{p(\theta|m)}\, \mathrm{d}\theta \;. \tag{3}$$

Sources:

Metadata: ID: D115 | shortcut: vblme | author: JoramSoch | date: 2020-11-25, 08:10.

3.2 Log family evidence

3.2.1 Definition

Definition: Let f be a family of M generative models ($\rightarrow$ Definition I/5.1.1) $m_1, \ldots, m_M$, such that the following statement holds true:

$$f \Leftrightarrow m_1 \vee \ldots \vee m_M \;. \tag{1}$$

Then, the family evidence of f is the weighted average of the model evidences ($\rightarrow$ Definition I/5.1.9) of $m_1, \ldots, m_M$ where the weights are the within-family prior model probabilities ($\rightarrow$ Definition I/5.1.3)

$$p(y|f) = \sum_{i=1}^{M} p(y|m_i)\, p(m_i|f) \;. \tag{2}$$

The log family evidence is given by the logarithm of the family evidence:

$$\text{LFE}(f) = \log p(y|f) = \log \sum_{i=1}^{M} p(y|m_i)\, p(m_i|f) \ . \tag{3}$$

Sources:
- Soch J, Allefeld C (2018): "MACS – a new SPM toolbox for model assessment, comparison and selection"; in: *Journal of Neuroscience Methods*, vol. 306, pp. 19-31, eq. 16; URL: https://www.sciencedirect.com/science/article/pii/S0165027018301468; DOI: 10.1016/j.jneumeth.2018.05.017.

Metadata: ID: D80 | shortcut: lfe | author: JoramSoch | date: 2020-07-13, 22:31.

3.2.2 Derivation

Theorem: Let f be a family of M generative models ($\to$ Definition I/5.1.1) $m_1, \ldots, m_M$ with model evidences ($\to$ Definition I/5.1.9) $p(y|m_1), \ldots, p(y|m_M)$. Then, the log family evidence ($\to$ Definition IV/3.2.1)

$$\text{LFE}(f) = \log p(y|f) \tag{1}$$

can be expressed as

$$\text{LFE}(f) = \log \sum_{i=1}^{M} p(y|m_i)\, p(m_i|f) \tag{2}$$

where $p(m_i|f)$ are the within-family ($\to$ Definition IV/3.2.1) prior ($\to$ Definition I/5.1.3) model ($\to$ Definition I/5.1.1) probabilities ($\to$ Definition I/1.2.1).

Proof: We will assume "prior addivivity"

$$p(f) = \sum_{i=1}^{M} p(m_i) \tag{3}$$

and "posterior additivity" for family probabilities:

$$p(f|y) = \sum_{i=1}^{M} p(m_i|y) \tag{4}$$

Bayes' theorem ($\to$ Proof I/5.3.1) for the family evidence ($\to$ Definition IV/3.2.1) gives

$$p(y|f) = \frac{p(f|y)\, p(y)}{p(f)} \ . \tag{5}$$

Applying (3) and (4), we have

$$p(y|f) = \frac{\sum_{i=1}^{M} p(m_i|y)\, p(y)}{\sum_{i=1}^{M} p(m_i)} \ . \tag{6}$$

Bayes' theorem ($\to$ Proof I/5.3.1) for the model evidence ($\to$ Definition IV/3.2.1) gives

$$p(y|m_i) = \frac{p(m_i|y)\, p(y)}{p(m_i)} \tag{7}$$

which can be rearranged into

$$p(m_i|y)\,p(y) = p(y|m_i)\,p(m_i)\;. \tag{8}$$

Plugging (8) into (6), we have

$$
\begin{aligned}
p(y|f) &= \frac{\sum_{i=1}^{M} p(y|m_i)\,p(m_i)}{\sum_{i=1}^{M} p(m_i)} \\
&= \sum_{i=1}^{M} p(y|m_i) \cdot \frac{p(m_i)}{\sum_{i=1}^{M} p(m_i)} \\
&= \sum_{i=1}^{M} p(y|m_i) \cdot \frac{p(m_i, f)}{p(f)} \\
&= \sum_{i=1}^{M} p(y|m_i) \cdot p(m_i|f)\;.
\end{aligned}
\tag{9}
$$

Equation (2) follows by logarithmizing both sides of (9).

3.2.3   Calculation from log model evidences

Theorem: Let $m_1, \ldots, m_M$ be M statistical models with log model evidences ($\rightarrow$ Definition IV/3.1.1) $\mathrm{LME}(m_1), \ldots, \mathrm{LME}(m_M)$ and belonging to F mutually exclusive model families $f_1, \ldots, f_F$. Then, the log family evidences ($\rightarrow$ Definition IV/3.2.1) are given by:

$$\mathrm{LFE}(f_j) = \log \sum_{m_i \in f_j} \left[\exp[\mathrm{LME}(m_i)] \cdot p(m_i|f_j) \right], \quad j = 1, \ldots, F, \tag{1}$$

where $p(m_i|f_j)$ are within-family ($\rightarrow$ Definition IV/3.2.1) prior ($\rightarrow$ Definition I/5.1.3) model ($\rightarrow$ Definition I/5.1.1) probabilities ($\rightarrow$ Definition I/1.2.1).

Proof: Let us consider the (unlogarithmized) family evidence $p(y|f_j)$. According to the law of marginal probability ($\rightarrow$ Definition I/1.2.3), this conditional probability is given by

$$p(y|f_j) = \sum_{m_i \in f_j} \left[p(y|m_i, f_j) \cdot p(m_i|f_j) \right]\;. \tag{2}$$

Because model families are mutually exclusive, it holds that $p(y|m_i, f_j) = p(y|m_i)$, such that

$$p(y|f_j) = \sum_{m_i \in f_j} \left[p(y|m_i) \cdot p(m_i|f_j) \right]\;. \tag{3}$$

Logarithmizing transforms the family evidence $p(y|f_j)$ into the log family evidence $\mathrm{LFE}(f_j)$:

$$\text{LFE}(f_j) = \log \sum_{m_i \in f_j} [p(y|m_i) \cdot p(m_i|f_j)] \ . \tag{4}$$

The definition of the log model evidence ($\to$ Definition IV/3.1.1)

$$\text{LME}(m) = \log p(y|m) \tag{5}$$

can be exponentiated to then read

$$\exp[\text{LME}(m)] = p(y|m) \tag{6}$$

and applying (6) to (4), we finally have:

$$\text{LFE}(f_j) = \log \sum_{m_i \in f_j} [\exp[\text{LME}(m_i)] \cdot p(m_i|f_j)] \ . \tag{7}$$

3.3   Log Bayes factor

3.3.1   Definition

Definition: Let there be two generative models ($\to$ Definition I/5.1.1) m_1 and m_2 which are mutually exclusive, but not necessarily collectively exhaustive:

$$\neg(m_1 \wedge m_2) \tag{1}$$

Then, the Bayes factor in favor of m_1 and against m_2 is the ratio of the model evidences ($\to$ Definition I/5.1.9) of m_1 and m_2:

$$\text{BF}_{12} = \frac{p(y|m_1)}{p(y|m_2)} \ . \tag{2}$$

The log Bayes factor is given by the logarithm of the Bayes factor:

$$\text{LBF}_{12} = \log \text{BF}_{12} = \log \frac{p(y|m_1)}{p(y|m_2)} \ . \tag{3}$$

Sources:
- Soch J, Allefeld C (2018): "MACS – a new SPM toolbox for model assessment, comparison and selection"; in: *Journal of Neuroscience Methods*, vol. 306, pp. 19-31, eq. 18; URL: https://www.sciencedirect.com/science/article/pii/S0165027018301468; DOI: 10.1016/j.jneumeth.2018.05.017.

Metadata: ID: D84 | shortcut: lbf | author: JoramSoch | date: 2020-07-22, 07:02.

3.3.2   Derivation

Theorem: Let there be two generative models ($\rightarrow$ Definition I/5.1.1) m_1 and m_2 with model evidences ($\rightarrow$ Definition I/5.1.9) $p(y|m_1)$ and $p(y|m_2)$. Then, the log Bayes factor ($\rightarrow$ Definition IV/3.3.1)

$$\mathrm{LBF}_{12} = \log \mathrm{BF}_{12} \tag{1}$$

can be expressed as

$$\mathrm{LBF}_{12} = \log \frac{p(y|m_1)}{p(y|m_2)} \;. \tag{2}$$

Proof: The Bayes factor ($\rightarrow$ Definition IV/3.4.1) is defined as the posterior ($\rightarrow$ Definition I/5.1.7) odds ratio ($\rightarrow$ Definition "odds") when both models ($\rightarrow$ Definition I/5.1.1) are equally likely apriori ($\rightarrow$ Definition I/5.1.3):

$$\mathrm{BF}_{12} = \frac{p(m_1|y)}{p(m_2|y)} \tag{3}$$

Plugging in the posterior odds ratio according to Bayes' rule ($\rightarrow$ Proof I/5.3.2), we have

$$\mathrm{BF}_{12} = \frac{p(y|m_1)}{p(y|m_2)} \cdot \frac{p(m_1)}{p(m_2)} \;. \tag{4}$$

When both models are equally likely apriori, the prior ($\rightarrow$ Definition I/5.1.3) odds ratio ($\rightarrow$ Definition "odds") is one, such that

$$\mathrm{BF}_{12} = \frac{p(y|m_1)}{p(y|m_2)} \;. \tag{5}$$

Equation (2) follows by logarithmizing both sides of (5).

3.3.3   Calculation from log model evidences

Theorem: Let m_1 and m_2 be two statistical models with log model evidences ($\rightarrow$ Definition IV/3.1.1) $\mathrm{LME}(m_1)$ and $\mathrm{LME}(m_2)$. Then, the log Bayes factor ($\rightarrow$ Definition IV/3.3.1) in favor of model m_1 and against model m_2 is the difference of the log model evidences:

$$\mathrm{LBF}_{12} = \mathrm{LME}(m_1) - \mathrm{LME}(m_2) \;. \tag{1}$$

Proof: The Bayes factor ($\rightarrow$ Definition IV/3.4.1) is defined as the ratio of the model evidences ($\rightarrow$ Definition I/5.1.9) of m_1 and m_2

$$\mathrm{BF}_{12} = \frac{p(y|m_1)}{p(y|m_2)} \tag{2}$$

and the log Bayes factor ($\rightarrow$ Definition IV/3.3.1) is defined as the logarithm of the Bayes factor

$$\text{LBF}_{12} = \log \text{BF}_{12} = \log \frac{p(y|m_1)}{p(y|m_2)} \ . \tag{3}$$

With the definition of the log model evidence ($\rightarrow$ Definition IV/3.1.1)

$$\text{LME}(m) = \log p(y|m) \tag{4}$$

the log Bayes factor can be expressed as:
Resolving the logarithm and applying the definition of the log model evidence ($\rightarrow$ Definition IV/3.1.1), we finally have:

$$\begin{aligned}
\text{LBF}_{12} &= \log p(y|m_1) - \log p(y|m_2) \\
&= \text{LME}(m_1) - \text{LME}(m_2) \ .
\end{aligned} \tag{5}$$

Sources:
- Soch J, Allefeld C (2018): "MACS – a new SPM toolbox for model assessment, comparison and selection"; in: *Journal of Neuroscience Methods*, vol. 306, pp. 19-31, eq. 18; URL: https://www.sciencedirect.com/science/article/pii/S0165027018301468; DOI: 10.1016/j.jneumeth.2018.05.017.

3.4   Bayes factor

3.4.1   Definition

Definition: Consider two competing generative models ($\rightarrow$ Definition I/5.1.1) m_1 and m_2 for observed data y. Then the Bayes factor in favor m_1 over m_2 is the ratio of marginal likelihoods ($\rightarrow$ Definition I/5.1.9) of m_1 and m_2:

$$\text{BF}_{12} = \frac{p(y \mid m_1)}{p(y \mid m_2)}. \tag{1}$$

Note that by Bayes' theorem ($\rightarrow$ Proof I/5.3.1), the ratio of posterior model probabilities ($\rightarrow$ Definition IV/3.5.1) (i.e., the posterior model odds) can be written as

$$\frac{p(m_1 \mid y)}{p(m_2 \mid y)} = \frac{p(m_1)}{p(m_2)} \cdot \frac{p(y \mid m_1)}{p(y \mid m_2)}, \tag{2}$$

or equivalently by (1),

$$\frac{p(m_1 \mid y)}{p(m_2 \mid y)} = \frac{p(m_1)}{p(m_2)} \cdot \text{BF}_{12}. \tag{3}$$

In other words, the Bayes factor can be viewed as the factor by which the prior model odds are updated (after observing data y) to posterior model odds – which is also expressed by Bayes' rule ($\rightarrow$ Proof I/5.3.2).

- Kass, Robert E. and Raftery, Adrian E. (1995): "Bayes Factors"; in: *Journal of the American Statistical Association*, vol. 90, no. 430, pp. 773-795; URL: https://dx.doi.org/10.1080/01621459.1995.10476572; DOI: 10.1080/01621459.1995.10476572.

Metadata: ID: D92 | shortcut: bf | author: tomfaulkenberry | date: 2020-08-26, 12:00.

3.4.2   Transitivity

Theorem: Consider three competing models ($\rightarrow$ Definition I/5.1.1) m_1, m_2, and $m3$ for observed data y. Then the Bayes factor ($\rightarrow$ Definition IV/3.4.1) for m_1 over m_3 can be written as:

$$\mathrm{BF}_{13} = \mathrm{BF}_{12} \cdot \mathrm{BF}_{23}. \tag{1}$$

Proof: By definition ($\rightarrow$ Definition IV/3.4.1), the Bayes factor BF_{13} is the ratio of marginal likelihoods of data y over m_1 and m_3, respectively. That is,

$$\mathrm{BF}_{13} = \frac{p(y \mid m_1)}{p(y \mid m_3)}. \tag{2}$$

We can equivalently write

$$
\begin{aligned}
\mathrm{BF}_{13} &\overset{(2)}{=} \frac{p(y \mid m_1)}{p(y \mid m_3)} \\
&= \frac{p(y \mid m_1)}{p(y \mid m_3)} \cdot \frac{p(y \mid m_2)}{p(y \mid m_2)} \\
&= \frac{p(y \mid m_1)}{p(y \mid m_2)} \cdot \frac{p(y \mid m_2)}{p(y \mid m_3)} \\
&\overset{(2)}{=} \mathrm{BF}_{12} \cdot \mathrm{BF}_{23},
\end{aligned}
\tag{3}
$$

which completes the proof of (1).

3.4.3   Computation using Savage-Dickey Density Ratio

Theorem: Consider two competing models ($\rightarrow$ Definition I/5.1.1) on data y containing parameters δ and φ, namely $m_0 : \delta = \delta_0, \varphi$ and $m_1 : \delta, \varphi$. In this context, we say that δ is a parameter of interest, φ is a nuisance parameter (i.e., common to both models), and m_0 is a sharp point hypothesis nested within m_1. Suppose further that the prior for the nuisance parameter φ in m_0 is equal to the prior for φ in m_1 after conditioning on the restriction – that is, $p(\varphi \mid m_0) = p(\varphi \mid \delta = \delta_0, m_1)$. Then the Bayes factor ($\rightarrow$ Definition IV/3.4.1) for m_0 over m_1 can be computed as:

$$\mathrm{BF}_{01} = \frac{p(\delta = \delta_0 \mid y, m_1)}{p(\delta = \delta_0 \mid m_1)}. \tag{1}$$

Proof: By definition ($\to$ Definition IV/3.4.1), the Bayes factor BF_{01} is the ratio of marginal likelihoods of data y over m_0 and m_1, respectively. That is,

$$\mathrm{BF}_{01} = \frac{p(y \mid m_0)}{p(y \mid m_1)}. \tag{2}$$

The key idea in the proof is that we can use a "change of variables" technique to express BF_{01} entirely in terms of the "encompassing" model m_1. This proceeds by first unpacking the marginal likelihood ($\to$ Definition I/5.1.9) for m_0 over the nuisance parameter φ and then using the fact that m_0 is a sharp hypothesis nested within m_1 to rewrite everything in terms of m_1. Specifically,

$$
\begin{aligned}
p(y \mid m_0) &= \int p(y \mid \varphi, m_0)\, p(\varphi \mid m_0)\, \mathrm{d}\varphi \\
&= \int p(y \mid \varphi, \delta = \delta_0, m_1)\, p(\varphi \mid \delta = \delta_0, m_1)\, \mathrm{d}\varphi \\
&= p(y \mid \delta = \delta_0, m_1).
\end{aligned} \tag{3}
$$

By Bayes' theorem ($\to$ Proof I/5.3.1), we can rewrite this last line as

$$p(y \mid \delta = \delta_0, m_1) = \frac{p(\delta = \delta_0 \mid y, m_1)\, p(y \mid m_1)}{p(\delta = \delta_0 \mid m_1)}. \tag{4}$$

Thus we have

$$
\begin{aligned}
\mathrm{BF}_{01} &\overset{(2)}{=} \frac{p(y \mid m_0)}{p(y \mid m_1)} \\
&= p(y \mid m_0) \cdot \frac{1}{p(y \mid m_1)} \\
&\overset{(3)}{=} p(y \mid \delta = \delta_0, m_1) \cdot \frac{1}{p(y \mid m_1)} \\
&\overset{(4)}{=} \frac{p(\delta = \delta_0 \mid y, m_1)\, p(y \mid m_1)}{p(\delta = \delta_0 \mid m_1)} \cdot \frac{1}{p(y \mid m_1)} \\
&= \frac{p(\delta = \delta_0 \mid y, m_1)}{p(\delta = \delta_0 \mid m_1)},
\end{aligned} \tag{5}
$$

which completes the proof of (1).

3.4.4   Computation using Encompassing Prior Method

Theorem: Consider two models m_1 and m_e, where m_1 is nested within an encompassing model ($\rightarrow$ Definition IV/3.4.5) m_e via an inequality constraint on some parameter θ, and θ is unconstrained under m_e. Then, the Bayes factor ($\rightarrow$ Definition IV/3.4.1) is

$$\mathrm{BF}_{1e} = \frac{c}{d} = \frac{1/d}{1/c} \tag{1}$$

where $1/d$ and $1/c$ represent the proportions of the posterior and prior of the encompassing model, respectively, that are in agreement with the inequality constraint imposed by the nested model m_1.

Proof: Consider first that for any model m_1 on data y with parameter θ, Bayes' theorem ($\rightarrow$ Proof I/5.3.1) implies

$$p(\theta \mid y, m_1) = \frac{p(y \mid \theta, m_1) \cdot p(\theta \mid m_1)}{p(y \mid m_1)}. \tag{2}$$

Rearranging equation (2) allows us to write the marginal likelihood ($\rightarrow$ Definition I/5.1.9) for y under m_1 as

$$p(y \mid m_1) = \frac{p(y \mid \theta, m_1) \cdot p(\theta \mid m_1)}{p(\theta \mid y, m_1)}. \tag{3}$$

Taking the ratio of the marginal likelihoods for m_1 and the encompassing model ($\rightarrow$ Definition IV/3.4.5) m_e yields the following Bayes factor ($\rightarrow$ Definition IV/3.4.1):

$$\mathrm{BF}_{1e} = \frac{p(y \mid \theta, m_1) \cdot p(\theta \mid m_1)/p(\theta \mid y, m_1)}{p(y \mid \theta, m_e) \cdot p(\theta \mid m_e)/p(\theta \mid y, m_e)}. \tag{4}$$

Now, both the constrained model m_1 and the encompassing model ($\rightarrow$ Definition IV/3.4.5) m_e contain the same parameter vector θ. Choose a specific value of θ, say θ', that exists in the support of both models m_1 and m_e (we can do this, because m_1 is nested within m_e). Then, for this parameter value θ', we have $p(y \mid \theta', m_1) = p(y \mid \theta', m_e)$, so the expression for the Bayes factor in equation (4) reduces to an expression involving only the priors and posteriors for θ' under m_1 and m_e:

$$\mathrm{BF}_{1e} = \frac{p(\theta' \mid m_1)/p(\theta' \mid y, m_1)}{p(\theta' \mid m_e)/p(\theta' \mid y, m_e)}. \tag{5}$$

Because m_1 is nested within m_e via an inequality constraint, the prior $p(\theta' \mid m_1)$ is simply a truncation of the encompassing prior $p(\theta' \mid m_e)$. Thus, we can express $p(\theta' \mid m_1)$ in terms of the encompassing prior $p(\theta' \mid m_e)$ by multiplying the encompassing prior by an indicator function over m_1 and then normalizing the resulting product. That is,

$$
\begin{aligned}
p(\theta' \mid m_1) &= \frac{p(\theta' \mid m_e) \cdot I_{\theta' \in m_1}}{\int p(\theta' \mid m_e) \cdot I_{\theta' \in m_1} \, \mathrm{d}\theta'} \\
&= \left(\frac{I_{\theta' \in m_1}}{\int p(\theta' \mid m_e) \cdot I_{\theta' \in m_1} \, \mathrm{d}\theta'} \right) \cdot p(\theta' \mid m_e),
\end{aligned}
\tag{6}
$$

where $I_{\theta' \in m_1}$ is an indicator function. For parameters $\theta' \in m_1$, this indicator function is identically equal to 1, so the expression in parentheses reduces to a constant, say c, allowing us to write the prior as

$$p(\theta' \mid m_1) = c \cdot p(\theta' \mid m_e). \tag{7}$$

By similar reasoning, we can write the posterior as

$$p(\theta' \mid y, m_1) = \left(\frac{I_{\theta' \in m_1}}{\int p(\theta' \mid y, m_e) \cdot I_{\theta' \in m_1} \, d\theta'} \right) \cdot p(\theta' \mid y, m_e) = d \cdot p(\theta' \mid y, m_e). \tag{8}$$

Plugging (7) and (8) into (5), this gives us

$$\mathrm{BF}_{1e} = \frac{c \cdot p(\theta' \mid m_e)/d \cdot p(\theta' \mid y, m_e)}{p(\theta' \mid m_e)/p(\theta' \mid y, m_e)} = \frac{c}{d} = \frac{1/d}{1/c}, \tag{9}$$

which completes the proof. Note that by definition, $1/d$ represents the proportion of the posterior distribution for θ under the encompassing model ($\rightarrow$ Definition IV/3.4.5) m_e that agrees with the constraints imposed by m_1. Similarly, $1/c$ represents the proportion of the prior distribution for θ under the encompassing model ($\rightarrow$ Definition IV/3.4.5) m_e that agrees with the constraints imposed by m_1.

3.4.5 Encompassing model

Definition: Consider a family f of generative models ($\rightarrow$ Definition I/5.1.1) m on data y, where each $m \in f$ is defined by placing an inequality constraint on model parameter(s) θ (e.g., $m : \theta > 0$). Then the encompassing model m_e is constructed such that each m is nested within m_e and all inequality constraints on the parameter(s) θ are removed.

3.5 Posterior model probability

3.5.1 Definition

Definition: Let $m_1, \ldots, m_M$ be M statistical models ($\rightarrow$ Definition I/5.1.4) with model evidences ($\rightarrow$ Definition I/5.1.9) $p(y|m_1), \ldots, p(y|m_M)$ and prior probabilities ($\rightarrow$ Definition I/5.1.3) $p(m_1), \ldots, p(m_M)$.

Then, the conditional probability ($\rightarrow$ Definition I/1.2.4) of model m_i, given the data y, is called the posterior probability ($\rightarrow$ Definition I/5.1.7) of model m_i:

$$\mathrm{PP}(m_i) = p(m_i|y) \; . \tag{1}$$

Sources:
- Soch J, Allefeld C (2018): "MACS – a new SPM toolbox for model assessment, comparison and selection"; in: *Journal of Neuroscience Methods*, vol. 306, pp. 19-31, eq. 23; URL: https://www.sciencedirect.com/science/article/pii/S0165027018301468; DOI: 10.1016/j.jneumeth.2018.05.017.

Metadata: ID: D87 | shortcut: pmp | author: JoramSoch | date: 2020-07-28, 03:30.

3.5.2   Derivation

Theorem: Let there be a set of generative models ($\rightarrow$ Definition I/5.1.1) $m_1, \ldots, m_M$ with model evidences ($\rightarrow$ Definition I/5.1.9) $p(y|m_1), \ldots, p(y|m_M)$ and prior probabilities ($\rightarrow$ Definition I/5.1.3) $p(m_1), \ldots, p(m_M)$. Then, the posterior probability ($\rightarrow$ Definition IV/3.5.1) of model m_i is given by

$$p(m_i|y) = \frac{p(y|m_i)\,p(m_i)}{\sum_{j=1}^{M} p(y|m_j)\,p(m_j)}, \; i = 1, \ldots, M \; . \tag{1}$$

Proof: From Bayes' theorem ($\rightarrow$ Proof I/5.3.1), the posterior model probability ($\rightarrow$ Definition IV/3.5.1) of the i-th model can be derived as

$$p(m_i|y) = \frac{p(y|m_i)\,p(m_i)}{p(y)} \; . \tag{2}$$

Using the law of marginal probability ($\rightarrow$ Definition I/1.2.3), the denominator can be rewritten, such that

$$p(m_i|y) = \frac{p(y|m_i)\,p(m_i)}{\sum_{j=1}^{M} p(y, m_j)} \; . \tag{3}$$

Finally, using the law of conditional probability ($\rightarrow$ Definition I/1.2.4), we have

$$p(m_i|y) = \frac{p(y|m_i)\,p(m_i)}{\sum_{j=1}^{M} p(y|m_j)\,p(m_j)} \; . \tag{4}$$

- original work

Metadata: ID: P139 | shortcut: pmp-der | author: JoramSoch | date: 2020-07-28, 03:58.

3.5.3   Calculation from Bayes factors

Theorem: Let $m_0, m_1, \ldots, m_M$ be $M + 1$ statistical models with model evidences ($\rightarrow$ Definition IV/3.1.1) $p(y|m_0), p(y|m_1), \ldots, p(y|m_M)$. Then, the posterior model probabilities ($\rightarrow$ Definition IV/3.5.1) of the models $m_1, \ldots, m_M$ are given by

$$p(m_i|y) = \frac{\text{BF}_{i,0} \cdot \alpha_i}{\sum_{j=1}^{M} \text{BF}_{j,0} \cdot \alpha_j}, \quad i = 1, \dots, M , \tag{1}$$

where $\text{BF}_{i,0}$ is the Bayes factor ($\to$ Definition IV/3.4.1) comparing model m_i with m_0 and α_i is the prior ($\to$ Definition I/5.1.3) odds ratio ($\to$ Definition "odds") of model m_i against m_0.

Proof: Define the Bayes factor ($\to$ Definition IV/3.4.1) for m_i

$$\text{BF}_{i,0} = \frac{p(y|m_i)}{p(y|m_0)} \tag{2}$$

and prior odds ratio of m_i against m_0

$$\alpha_i = \frac{p(m_i)}{p(m_0)} . \tag{3}$$

The posterior model probability ($\to$ Proof IV/3.5.2) of m_i is given by

$$p(m_i|y) = \frac{p(y|m_i) \cdot p(m_i)}{\sum_{j=1}^{M} p(y|m_j) \cdot p(m_j)} . \tag{4}$$

Now applying (2) and (3) to (4), we have

$$
\begin{aligned}
p(m_i|y) &= \frac{\text{BF}_{i,0}\, p(y|m_0) \cdot \alpha_i\, p(m_0)}{\sum_{j=1}^{M} \text{BF}_{j,0}\, p(y|m_0) \cdot \alpha_j\, p(m_0)} \\
&= \frac{[p(y|m_0)\, p(m_0)]\, \text{BF}_{i,0} \cdot \alpha_i}{[p(y|m_0)\, p(m_0)] \sum_{j=1}^{M} \text{BF}_{j,0} \cdot \alpha_j} ,
\end{aligned}
\tag{5}
$$

such that

$$p(m_i|y) = \frac{\text{BF}_{i,0} \cdot \alpha_i}{\sum_{j=1}^{M} \text{BF}_{j,0} \cdot \alpha_j} . \tag{6}$$

3.5.4 Calculation from log Bayes factor

Theorem: Let m_1 and m_2 be two statistical models with the log Bayes factor ($\to$ Definition IV/3.3.1) LBF_{12} in favor of model m_1 and against model m_2. Then, if both models are equally likely apriori ($\to$ Definition I/5.1.3), the posterior model probability ($\to$ Definition IV/3.5.1) of m_1 is

$$p(m_1|y) = \frac{\exp(\text{LBF}_{12})}{\exp(\text{LBF}_{12}) + 1} . \tag{1}$$

Proof: From Bayes' rule ($\rightarrow$ Proof I/5.3.2), the posterior odds ratio ($\rightarrow$ Definition "odds") is

$$\frac{p(m_1|y)}{p(m_2|y)} = \frac{p(y|m_1)}{p(y|m_2)} \cdot \frac{p(m_1)}{p(m_2)} . \tag{2}$$

When both models are equally likely apriori ($\rightarrow$ Definition I/5.1.3), the prior odds ratio ($\rightarrow$ Definition "odds") is one, such that

$$\frac{p(m_1|y)}{p(m_2|y)} = \frac{p(y|m_1)}{p(y|m_2)} . \tag{3}$$

Now the right-hand side corresponds to the Bayes factor ($\rightarrow$ Definition IV/3.4.1), therefore

$$\frac{p(m_1|y)}{p(m_2|y)} = \mathrm{BF}_{12} . \tag{4}$$

Because the two posterior model probabilities ($\rightarrow$ Definition IV/3.5.1) add up to 1, we have

$$\frac{p(m_1|y)}{1 - p(m_1|y)} = \mathrm{BF}_{12} . \tag{5}$$

Now rearranging for the posterior probability ($\rightarrow$ Definition IV/3.5.1), this gives

$$p(m_1|y) = \frac{\mathrm{BF}_{12}}{\mathrm{BF}_{12} + 1} . \tag{6}$$

Because the log Bayes factor is the logarithm of the Bayes factor ($\rightarrow$ Definition IV/3.3.1), we finally have

$$p(m_1|y) = \frac{\exp(\mathrm{LBF}_{12})}{\exp(\mathrm{LBF}_{12}) + 1} . \tag{7}$$

3.5.5 Calculation from log model evidences

Theorem: Let $m_1, \ldots, m_M$ be M statistical models with log model evidences ($\rightarrow$ Definition IV/3.1.1) $\mathrm{LME}(m_1), \ldots, \mathrm{LME}(m_M)$. Then, the posterior model probabilities ($\rightarrow$ Definition IV/3.5.1) are given by:

$$p(m_i|y) = \frac{\exp[\mathrm{LME}(m_i)] \, p(m_i)}{\sum_{j=1}^{M} \exp[\mathrm{LME}(m_j)] \, p(m_j)}, \quad i = 1, \ldots, M , \tag{1}$$

where $p(m_i)$ are prior ($\rightarrow$ Definition I/5.1.3) model probabilities.

Proof: The posterior model probability ($\rightarrow$ Proof IV/3.5.2) can be derived as

$$p(m_i|y) = \frac{p(y|m_i)\,p(m_i)}{\sum_{j=1}^{M} p(y|m_j)\,p(m_j)} \ . \tag{2}$$

The definition of the log model evidence ($\rightarrow$ Definition IV/3.1.1)

$$\text{LME}(m) = \log p(y|m) \tag{3}$$

can be exponentiated to then read

$$\exp\left[\text{LME}(m)\right] = p(y|m) \tag{4}$$

and applying (4) to (2), we finally have:

$$p(m_i|y) = \frac{\exp[\text{LME}(m_i)]\,p(m_i)}{\sum_{j=1}^{M} \exp[\text{LME}(m_j)]\,p(m_j)} \ . \tag{5}$$

3.6 Bayesian model averaging

3.6.1 Definition

Definition: Let $m_1, \ldots, m_M$ be M statistical models ($\rightarrow$ Definition I/5.1.4) with posterior model probabilities ($\rightarrow$ Definition IV/3.5.1) $p(m_1|y), \ldots, p(m_M|y)$ and posterior distributions ($\rightarrow$ Definition I/5.1.7) $p(\theta|y, m_1), \ldots, p(\theta|y, m_M)$. Then, Bayesian model averaging (BMA) consists in finding the marginal ($\rightarrow$ Definition I/1.3.3) posterior ($\rightarrow$ Definition I/5.1.7) density ($\rightarrow$ Definition I/1.4.4), conditional ($\rightarrow$ Definition I/1.2.4) on the measured data y, but unconditional ($\rightarrow$ Definition I/1.2.3) on the modelling approach m:

$$p(\theta|y) = \sum_{i=1}^{M} p(\theta|y, m_i) \cdot p(m_i|y) \ . \tag{1}$$

Sources:
- Hoeting JA, Madigan D, Raftery AE, Volinsky CT (1999): "Bayesian Model Averaging: A Tutorial"; in: *Statistical Science*, vol. 14, no. 4, pp. 382–417, eq. 1; URL: https://projecteuclid.org/euclid.ss/1009212519; DOI: 10.1214/ss/1009212519.

Metadata: ID: D89 | shortcut: bma | author: JoramSoch | date: 2020-08-03, 21:34.

3.6.2   Derivation

Theorem: Let $m_1, \ldots, m_M$ be M statistical models ($\to$ Definition I/5.1.4) with posterior model probabilities ($\to$ Definition IV/3.5.1) $p(m_1|y), \ldots, p(m_M|y)$ and posterior distributions ($\to$ Definition I/5.1.7) $p(\theta|y, m_1), \ldots, p(\theta|y, m_M)$. Then, the marginal ($\to$ Definition I/1.3.3) posterior ($\to$ Definition I/5.1.7) density ($\to$ Definition I/1.4.4), conditional ($\to$ Definition I/1.2.4) on the measured data y, but unconditional ($\to$ Definition I/1.2.3) on the modelling approach m, is given by:

$$ p(\theta|y) = \sum_{i=1}^{M} p(\theta|y, m_i) \cdot p(m_i|y) \; . \tag{1} $$

Proof: Using the law of marginal probability ($\to$ Definition I/1.2.3), the probability distribution of the shared parameters θ conditional ($\to$ Definition I/1.2.4) on the measured data y can be obtained by marginalizing ($\to$ Definition I/1.2.3) over the discrete random variable ($\to$ Definition I/1.1.3) model m:

$$ p(\theta|y) = \sum_{i=1}^{M} p(\theta, m_i|y) \; . \tag{2} $$

Using the law of the conditional probability ($\to$ Definition I/1.2.4), the summand can be expanded to give

$$ p(\theta|y) = \sum_{i=1}^{M} p(\theta|y, m_i) \cdot p(m_i|y) \tag{3} $$

where $p(\theta|y, m_i)$ is the posterior distribution ($\to$ Definition I/5.1.7) of the i-th model and $p(m_i|y)$ happens to be the posterior probability ($\to$ Definition IV/3.5.1) of the i-th model.

3.6.3   Calculation from log model evidences

Theorem: Let $m_1, \ldots, m_M$ be M statistical models ($\to$ Definition I/5.1.4) describing the same measured data y with log model evidences ($\to$ Definition IV/3.1.1) $\mathrm{LME}(m_1), \ldots, \mathrm{LME}(m_M)$ and shared model parameters θ. Then, Bayesian model averaging ($\to$ Definition IV/3.6.1) determines the following posterior distribution over θ:

$$ p(\theta|y) = \sum_{i=1}^{M} p(\theta|m_i, y) \cdot \frac{\exp[\mathrm{LME}(m_i)]\, p(m_i)}{\sum_{j=1}^{M} \exp[\mathrm{LME}(m_j)]\, p(m_j)} \; , \tag{1} $$

where $p(\theta|m_i, y)$ is the posterior distributions over θ obtained using m_i.

Proof: According to the law of marginal probability ($\to$ Definition I/1.2.3), the probability of the shared parameters θ conditional on the measured data y can be obtained ($\to$ Proof IV/3.6.2) by marginalizing over the discrete variable model m:

$$p(\theta|y) = \sum_{i=1}^{M} p(\theta|m_i, y) \cdot p(m_i|y) \;, \tag{2}$$

where $p(m_i|y)$ is the posterior probability ($\to$ Definition IV/3.5.1) of the i-th model. One can express posterior model probabilities in terms of log model evidences ($\to$ Proof IV/3.5.5) as

$$p(m_i|y) = \frac{\exp[\mathrm{LME}(m_i)]\, p(m_i)}{\sum_{j=1}^{M} \exp[\mathrm{LME}(m_j)]\, p(m_j)} \tag{3}$$

and by plugging (3) into (2), one arrives at (1).

P133	blr-pp	Posterior probability of the alternative hypothesis for Bayesian linear regression	JoramSoch	2020-07-17	259
P134	blr-pcr	Posterior credibility region against the omnibus null hypothesis for Bayesian linear regression	JoramSoch	2020-07-17	261
P135	mlr-idem	Projection matrix and residual-forming matrix are idempotent	JoramSoch	2020-07-22	248
P136	mlr-wls2	Weighted least squares for multiple linear regression	JoramSoch	2020-07-22	250
P137	lbf-der	Derivation of the log Bayes factor	JoramSoch	2020-07-22	326
P138	mean-lotus	Law of the unconscious statistician	JoramSoch	2020-07-22	32
P139	pmp-der	Derivation of the posterior model probability	JoramSoch	2020-07-28	332
P140	duni-pmf	Probability mass function of the discrete uniform distribution	JoramSoch	2020-07-28	106
P141	duni-cdf	Cumulative distribution function of the discrete uniform distribution	JoramSoch	2020-07-28	107
P142	duni-qf	Quantile function of the discrete uniform distribution	JoramSoch	2020-07-28	108
P143	bma-der	Derivation of Bayesian model averaging	JoramSoch	2020-08-03	336
P144	matn-trans	Transposition of a matrix-normal random variable	JoramSoch	2020-08-03	202
P145	matn-ltt	Linear transformation theorem for the matrix-normal distribution	JoramSoch	2020-08-03	203
P146	ng-cond	Conditional distributions of the normal-gamma distribution	JoramSoch	2020-08-05	194
P147	kl-nonsymm	Non-symmetry of the Kullback-Leibler divergence	JoramSoch	2020-08-11	77
P148	kl-conv	Convexity of the Kullback-Leibler divergence	JoramSoch	2020-08-11	78

P149	ent-conc	Concavity of the Shannon entropy	JoramSoch	2020-08-11	58
P150	entcross-conv	Convexity of the cross-entropy	JoramSoch	2020-08-11	60
P151	poiss-mean	Mean of the Poisson distribution	JoramSoch	2020-08-19	113
P152	norm-fwhm	Full width at half maximum for the normal distribution	JoramSoch	2020-08-19	142
P153	mom-mgf	Moment in terms of moment-generating function	JoramSoch	2020-08-19	51
P154	mgf-ltt	Linear transformation theorem for the moment-generating function	JoramSoch	2020-08-19	22
P155	mgf-lincomb	Moment-generating function of linear combination of independent random variables	JoramSoch	2020-08-19	23
P156	bf-sddr	Savage-Dickey Density Ratio for computing Bayes Factors	tomfaulkenberry	2020-08-26	328
P157	bf-ep	Encompassing Prior Method for computing Bayes Factors	tomfaulkenberry	2020-09-02	330
P158	cov-ind	Covariance of independent random variables	JoramSoch	2020-09-03	42
P159	mblr-prior	Conjugate prior distribution for multivariate Bayesian linear regression	JoramSoch	2020-09-03	267
P160	mblr-post	Posterior distribution for multivariate Bayesian linear regression	JoramSoch	2020-09-03	269
P161	mblr-lme	Log model evidence for multivariate Bayesian linear regression	JoramSoch	2020-09-03	271
P162	wald-pdf	Probability density function of the Wald distribution	tomfaulkenberry	2020-09-04	174
P163	bf-trans	Transitivity of Bayes Factors	tomfaulkenberry	2020-09-07	328
P164	gibbs-ineq	Gibbs' inequality	JoramSoch	2020-09-09	61
P165	logsum-ineq	Log sum inequality	JoramSoch	2020-09-09	62
P166	kl-nonneg2	Non-negativity of the Kullback-Leibler divergence	JoramSoch	2020-09-09	76
P167	momcent-1st	First central moment is zero	JoramSoch	2020-09-09	54

P168	wald-mgf	Moment-generating function of the Wald distribution	tomfaulkenberry	2020-09-13	174
P169	wald-mean	Mean of the Wald distribution	tomfaulkenberry	2020-09-13	176
P170	wald-var	Variance of the Wald distribution	tomfaulkenberry	2020-09-13	177
P171	momraw-1st	First raw moment is mean	JoramSoch	2020-10-08	53
P172	momraw-2nd	Relationship between second raw moment, variance and mean	JoramSoch	2020-10-08	53
P173	momcent-2nd	Second central moment is variance	JoramSoch	2020-10-08	55
P174	chi2-gam	Chi-square distribution is a special case of gamma distribution	kjpetrykowski	2020-10-12	164
P175	chi2-mom	Moments of the chi-square distribution	kjpetrykowski	2020-10-13	167
P176	norm-snorm2	Relation between normal distribution and standard normal distribution	JoramSoch	2020-10-15	127
P177	gam-sgam2	Relation between gamma distribution and standard gamma distribution	JoramSoch	2020-10-15	148
P178	gam-cdf	Cumulative distribution function of the gamma distribution	JoramSoch	2020-10-15	150
P179	gam-xlogx	Expected value of x times ln(x) for a gamma distribution	JoramSoch	2020-10-15	156
P180	norm-snorm3	Relation between normal distribution and standard normal distribution	JoramSoch	2020-10-22	128
P181	dir-ep	Exceedance probabilities for the Dirichlet distribution	JoramSoch	2020-10-22	197
P182	dir-mle	Maximum likelihood estimation for Dirichlet-distributed data	JoramSoch	2020-10-22	290
P183	cdf-sifct	Cumulative distribution function of a strictly increasing function of a random variable	JoramSoch	2020-10-29	15
P184	pmf-sifct	Probability mass function of a strictly increasing function of a discrete random variable	JoramSoch	2020-10-29	10

P185	pdf-sifct	Probability density function of a strictly increasing function of a continuous random variable	JoramSoch	2020-10-29	12
P186	cdf-sdfct	Cumulative distribution function of a strictly decreasing function of a random variable	JoramSoch	2020-11-06	16
P187	pmf-sdfct	Probability mass function of a strictly decreasing function of a discrete random variable	JoramSoch	2020-11-06	10
P188	pdf-sdfct	Probability density function of a strictly decreasing function of a continuous random variable	JoramSoch	2020-11-06	13
P189	cdf-pmf	Cumulative distribution function in terms of probability mass function of a discrete random variable	JoramSoch	2020-11-12	17
P190	cdf-pdf	Cumulative distribution function in terms of probability density function of a continuous random variable	JoramSoch	2020-11-12	18
P191	pdf-cdf	Probability density function is first derivative of cumulative distribution function	JoramSoch	2020-11-12	14
P192	qf-cdf	Quantile function is inverse of strictly monotonically increasing cumulative distribution function	JoramSoch	2020-11-12	21
P193	norm-kl	Kullback-Leibler divergence for the normal distribution	JoramSoch	2020-11-19	144
P194	gam-qf	Quantile function of the gamma distribution	JoramSoch	2020-11-19	151
P195	beta-cdf	Cumulative distribution function of the beta distribution	JoramSoch	2020-11-19	170
P196	norm-gi	Gaussian integral	JoramSoch	2020-11-25	129
P197	chi2-pdf	Probability density function of the chi-square distribution	JoramSoch	2020-11-25	165
P198	beta-mgf	Moment-generating function of the beta distribution	JoramSoch	2020-11-25	169
P199	dent-inv	Invariance of the differential entropy under addition of a constant	JoramSoch	2020-12-02	64

P200	dent-add	Addition of the differential entropy upon multiplication with a constant	JoramSoch	2020-12-02	65
P201	ug-prior	Conjugate prior distribution for the univariate Gaussian	JoramSoch	2021-03-03	212
P202	ug-post	Posterior distribution for the univariate Gaussian	JoramSoch	2021-03-03	214
P203	ug-lme	Log model evidence for the univariate Gaussian	JoramSoch	2021-03-03	217
P204	ug-ttest1	One-sample t-test for independent observations	JoramSoch	2021-03-12	208
P205	ug-ttest2	Two-sample t-test for independent observations	JoramSoch	2021-03-12	210
P206	ug-ttestp	Paired t-test for dependent observations	JoramSoch	2021-03-12	211
P207	ugkv-mle	Maximum likelihood estimation for the univariate Gaussian with known variance	JoramSoch	2021-03-24	220
P208	ugkv-ztest1	One-sample z-test for independent observations	JoramSoch	2021-03-24	221
P209	ugkv-ztest2	Two-sample z-test for independent observations	JoramSoch	2021-03-24	223
P210	ugkv-ztestp	Paired z-test for dependent observations	JoramSoch	2021-03-24	224
P211	ugkv-prior	Conjugate prior distribution for the univariate Gaussian with known variance	JoramSoch	2021-03-24	225
P212	ugkv-post	Posterior distribution for the univariate Gaussian with known variance	JoramSoch	2021-03-24	227
P213	ugkv-lme	Log model evidence for the univariate Gaussian with known variance	JoramSoch	2021-03-24	229
P214	ugkv-anc	Accuracy and complexity for the univariate Gaussian with known variance	JoramSoch	2021-03-24	231
P215	ugkv-lbf	Log Bayes factor for the univariate Gaussian with known variance	JoramSoch	2021-03-24	232

P216	ugkv-lbfmean	Expectation of the log Bayes factor for the univariate Gaussian with known variance	JoramSoch	2021-03-24	233
P217	ugkv-cvlme	Cross-validated log model evidence for the univariate Gaussian with known variance	JoramSoch	2021-03-24	235
P218	ugkv-cvlbf	Cross-validated log Bayes factor for the univariate Gaussian with known variance	JoramSoch	2021-03-24	238
P219	ugkv-cvlbfmean	Expectation of the cross-validated log Bayes factor for the univariate Gaussian with known variance	JoramSoch	2021-03-24	239
P220	cdf-pit	Probability integral transform using cumulative distribution function	JoramSoch	2021-04-07	19
P221	cdf-itm	Inverse transformation method using cumulative distribution function	JoramSoch	2021-04-07	19
P222	cdf-dt	Distributional transformation using cumulative distribution function	JoramSoch	2021-04-07	20
P223	ug-mle	Maximum likelihood estimation for the univariate Gaussian	JoramSoch	2021-04-16	206
P224	poissexp-mle	Maximum likelihood estimation for the Poisson distribution with exposure values	JoramSoch	2021-04-16	280
P225	poiss-prior	Conjugate prior distribution for Poisson-distributed data	JoramSoch	2020-04-21	276
P226	poiss-post	Posterior distribution for Poisson-distributed data	JoramSoch	2020-04-21	277
P227	poiss-lme	Log model evidence for Poisson-distributed data	JoramSoch	2020-04-21	278
P228	beta-mean	Mean of the beta distribution	JoramSoch	2021-04-29	171
P229	beta-var	Variance of the beta distribution	JoramSoch	2021-04-29	172
P230	poiss-var	Variance of the Poisson distribution	JoramSoch	2021-04-29	114

D127	hyp	Statistical hypothesis	JoramSoch	2021-03-19	89
D128	hyp-simp	Simple and composite hypothesis	JoramSoch	2021-03-19	89
D129	hyp-point	Point and set hypothesis	JoramSoch	2021-03-19	89
D130	test	Statistical hypothesis test	JoramSoch	2021-03-19	90
D131	tstat	Test statistic	JoramSoch	2021-03-19	92
D132	size	Size of a statistical test	JoramSoch	2021-03-19	92
D133	alpha	Significance level	JoramSoch	2021-03-19	93
D134	cval	Critical value	JoramSoch	2021-03-19	94
D135	pval	p-value	JoramSoch	2021-03-19	94
D136	ugkv	Univariate Gaussian with known variance	JoramSoch	2021-03-23	220
D137	power	Power of a statistical test	JoramSoch	2021-03-31	93
D138	hyp-tail	One-tailed and two-tailed hypothesis	JoramSoch	2021-03-31	90
D139	test-tail	One-tailed and two-tailed test	JoramSoch	2021-03-31	92

D140	dist-samp	Sampling distribution	JoramSoch	2021-03-31	9
D141	cdf-joint	Joint cumulative distribution function	JoramSoch	2020-04-07	20
D142	mean-samp	Sample mean	JoramSoch	2021-04-16	25
D143	var-samp	Sample variance	JoramSoch	2021-04-16	34
D144	cov-samp	Sample covariance	JoramSoch	2021-04-21	41
D145	prec	Precision	JoramSoch	2020-04-21	40
D146	f	F-distribution	JoramSoch	2020-04-21	167
D147	t	t-distribution	JoramSoch	2020-04-21	146
D148	mvt	Multivariate t-distribution	JoramSoch	2020-04-21	188
D149	eb	Empirical Bayes	JoramSoch	2021-04-29	103
D150	vb	Variational Bayes	JoramSoch	2021-04-29	104
D151	mome	Method-of-moments estimation	JoramSoch	2021-04-29	88

3 Proof by Topic

Q

R

4 Definition by Topic

A
- Akaike information criterion, 315
- Alternative hypothesis, 91

B
- Bayes factor, 327
- Bayesian information criterion, 315
- Bayesian model averaging, 335
- Bernoulli distribution, 109
- Beta distribution, 168
- Beta-distributed data, 288
- Binomial distribution, 110
- Binomial observations, 294

C
- Categorical distribution, 116
- Central moment, 54
- Chi-square distribution, 164
- Coefficient of determination, 309
- Conditional differential entropy, 66
- Conditional entropy, 59
- Conditional independence, 7
- Conditional probability distribution, 9
- Conjugate and non-conjugate prior distribution, 100
- Constant, 3
- Continuous uniform distribution, 120
- Correlation, 47
- Correlation matrix, 47
- Covariance, 40
- Covariance matrix, 43
- Critical value, 94
- Cross-entropy, 60
- Cross-validated log model evidence, 320
- Cumulant-generating function, 24
- Cumulative distribution function, 14

D
- Deviance information criterion, 317
- Differential cross-entropy, 67
- Differential entropy, 63
- Dirichlet distribution, 196
- Dirichlet-distributed data, 290
- Discrete and continuous random variable, 4
- Discrete uniform distribution, 106

E
- Empirical Bayes, 103

p
- p-value, 94

t
- t-distribution, 146
